the observed changes. By the end of the last century certain rules of structure in relation to pharma-
cological reactions had already been laid down.

The study of the doctrine of internal secretion provided the chemist and biochemist with a further
series of problems in their attempt to elucidate the structure of the body's own drugs.

Out of the former grew the science of chemotherapy, namely the building up of organic substances
capable of various therapeutic activities. Until comparatively recently however there has been no
chemotherapeutic counterpart to the study of hormones. The development of the study of synthetic
oestrogenic agents may perhaps indicate an entirely new line for therapeutic approach.

Applications are invited from duly qualified medical men for the appointment of Junior Assistant Medical Officer at the above hospital.

The Medical Officer appointed will be required to take duty in the Medical, Surgical, and Maternity Departments as directed by the Medical Superintendent.

The appointment will be for one year only and the salary offered is £100 per annum with the usual retainer of 10 shillings per week.

Previous medical experience is desirable. Applications stating age and qualifications and experience and accompanied by not more than three recent testimonials must be sent to the Medical Superintendent, City General Hospital, Sheffield 4.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE

The Secretary of State for the Colonies proposes to select within the next few months not less than 10 Medical Officers to fill vacancies the majority of which will occur in Tropical Africa or in Malaya

QUALIFICATIONS Candidates must be British subjects of European parentage under 35 years of age and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY Initial salaries vary from £600 to £700 and rise by increments to a maximum of between £1000 and £1200

PRIVATE PRACTICE Private practice is not allowed as of right but in the case of some appointments it is permitted on certain conditions

QUARTERS In Tropical Africa free quarters or an allowance in lieu, are provided. In Malaya quarters are provided at an annual rental not exceeding 6% of the officer's salary

PASSAGES Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages

TERMS OF APPOINTMENT The appointments are pensionable, subject to a probationary period which varies from two to three years

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE. Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas

DUTIES Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery in public health and in medical research

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, SW 1

ROYAL NAVAL MEDICAL SERVICE.

A number of vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1937

Candidates must not be above the age of 28 years and must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate Study

Copies of the regulations for entry and conditions of Service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, SW 1, and from the Deans of all Medical Schools

Applications for entry from intending candidates must be received not later than May 31st, 1937

THE ROYAL BOROUGH OF KENSINGTON

- 15 OUTLYING NORTHERN DISTRICT—Mixed-class PRACTICE, receipts last 12 months £1,290 including Panel of 1,000. Suitable flat above surgery premises. Inclusive rental £104 p.a. Premium 2 years purchase.
- 16 HOME COUNTIES—PARTNERSHIP—A SEVEN SIXTEENTHS SHARE with succession to the whole eventually is offered in sound old established Practice in growing district within easy reach of London. Gross cash receipts for immediate past 12 months approximately £2,700. Panel of 2,500. Moderate expenses and appointments worth over £200 p.a. Detached house on main road containing 4 bedrooms etc. with garden. Rent on lease £80 p.a.
- 17 SUSSEX—ATTRACTIVE DISTRICT NEAR SEA—PARTNERSHIP—A ONE FOURTH SHARE is offered (after preliminary assistance) for 6 to 12 months in old-established Practice having good scope. Gross cash receipts for last 12 months approximately £1,275. Panel of about 1,300. Appointments worth over £300. Choice of houses on rental for incoming partner. Premium 2 years purchase.
- 18 SURREY—RAPIDLY DEVELOPING AREA—Recently established PRACTICE producing for last 12 months £720 including Panel of 650. Suitable house can be purchased. Moderate premium. Ill-health reason for sale.
- 19 CO DURIHAM—Mixed-class PRACTICE producing about £987 p.a. including Panel of 1,310 and club bringing in about £5 per week. Suitable house available.
- 20 NORTH LONDON—Sound mixed class PRACTICE. Established over 40 years, producing last 12 months nearly £2,900. Substantial panel. Nice house in good repair. Rent £104 p.a.
- 21 NORTH LONDON—Old established PRACTICE producing about £700 p.a. including panel of nearly 600 patients. Suitable house ample accommodation and good garden. To rent at £100 p.a. Premium £1,200.
- 22 DEATH VACANCY—SOUTH COAST TOWN—PRACTICE producing about £250 p.a. Five years ago it was doing £1,000 p.a. but has decreased owing to ill health. Modernised house with ample accommodation. Price for freehold and practice £3,150.
- 23 WEST OF ENGLAND—Seaside resort combined with lovely country—good middle and better working-class PRACTICE, established over 50 years. Gross cash receipts average £1,670 approximately. About £650 is derived from panel and P.M.S. Fees 3/6 to 2/1. Well-built house with 3 sitting rooms and 6 bedrooms, good garden, tennis lawn and garage. Can be rented on lease.
- 24 LONDON WESTERN AREA—Mixed class PRACTICE in populous district. Gross cash receipts for last 12 months about £700 but capable of increase. Panel of 500. Well situated house with ample accommodation, will be put into thorough repair. Good garden. Price for Practice and house £2,500. £500 down.
- 25 WELSH BORDERS—Unopposed chiefly agricultural PRACTICE in beautiful district. Average gross cash receipts £913 p.a. (last year 1936). Panel produces about £370 p.a. and appointments worth about £172 p.a. Very low expenses. Suitable house in own grounds with tennis court, etc. containing 2 reception, 6 bedrooms, etc. Freehold for sale £1,200. £700 on mortgage. Premium £1,500.
- 26 WEST COAST OF SCOTLAND—Old-established mixed class non dispensing PRACTICE held by vendor many years. Gross cash receipts average about £1,000 p.a. Panel of 1,213. Appointments worth about £30 p.a. Fees 2/6 to 1/5. Purchaser can choose his own house. Good golf and other sport. Premium 11 years purchase.
- 27 CUMBERLAND—Old-established unopposed PRACTICE held by vendor who is retiring for 30 years. Gross cash receipts average about £800 p.a., including panel worth over £250 p.a., and appointments worth nearly £80 p.a. Suitable 8-roomed house with bathroom, surgery dispensary, etc., garden, garage. Rent £30 p.a. Shooting fishing golf etc. Premium 11 years purchase.
- 28 SOUTHERN RHODESIA—Hospital Town on Railway. Beautiful climate and country. Good-class prescribing PRACTICE, easily run. Visits 7/6 to 10/6. Midwifery £10 10s. 0d. Average income for past 5 years £1,900 p.a. Well appointed house with tennis court, garage, surgery etc. can be rented or bought. Good operating surgeon will greatly increase practice. Excellent schools. Sport of all kinds, big game shooting, fishing, etc. Income tax 6d. in the £. Premium £2,000 to include drugs, surgery fittings and furniture.
- 29 LONDON NORTH—Old-established chiefly working-class PRACTICE. Receipts for last 12 months approximately £1,603 with panel of about 2,700. Suitable accommodation can be rented at £92 p.a.
- 30 EASTERN COUNTIES—COUNTRY PARTNERSHIP—ONE THIRD SHARE available in mixed-class Practice over £2,500 p.a., including panel of nearly 1,800. House contains 2 reception, 4 bedrooms, large and attractive garden and good garage. Rent £55 p.a. Sport of all kinds. Premium 2 years purchase or pair offer.
- 31 SUSSEX COAST TOWN—PRACTICE established 45 years for disposal owing to retirement of Vendor. Present receipts about £600. There is stated to be scope for increase as receipts have fallen owing to Vendor's illness. Panel about 650. Large house can be rented at £150 or purchaser could probably choose own residence.
- 32 LONDON SOUTH EAST—Old-established PRACTICE producing about £1,830 p.a., including select panel of 500. Fees from 3/6. Suitable house available with 2 reception, 5 bedrooms, etc. Freehold for sale. Premium 2 years purchase.
- 33 SOUTH CORNWALL—FAVOURITE COAST TOWN—Well-established PRACTICE averaging over £1,100 p.a., including selected panel of about 350. Fees from 5/1. Good freehold house for sale or smaller house, available. Premium £2,000. Vendor retiring.
- 34 NORTH WALES—FAVOURITE SEASIDE RESORT—A ONE THIRD SHARE (with increase later) is offered after short preliminary assistance in old-established better-class practice producing about £3,400 p.a. Panel of 1,100. Suitable flat available for incoming partner who should be experienced. Premium 2 years purchase.
- 35 LONDON NORTH WEST—PARTNERSHIP—A ONE THIRD SHARE is for disposal in steadily increasing middle-class practice produced in last year £2,400. Small panel. Fees 7/6 to 2/1. Choice of houses. Premium £2,000.
- 36 RIVERSIDE TOWN—Well-established middle-class PRACTICE producing £1,200 p.a. Panel of 400 to 450 patients with ample accommodation. Premium £1,200.
- 37 MIDLANDS PARTNERSHIP—ONE HALF SHARE in mixed-class Practice in attractive district producing over £2,400 p.a. Panel of 1,300 and appointments worth about £130. Large house available or smaller one can be obtained. Premium 2 years purchase.
- 38 LONDON—SOUTH—EAST—Well established middle class increasing PRACTICE producing for last 12 months £1,270. Panel of 970. Fees 3/6 to 2/6. Scope for development as building is in progress. Good house in excellent condition, containing 2 reception, 5 sitting, 4 to 6 bedrooms, dressing room, etc. Price £500. Premium £1,400.
- 39 MIDLANDS—PARTNERSHIP—A SHARE representing approximately £1,300 p.a. with increase later is offered in exceptionally sound good middle-class practice averaging about £9,000 p.a. with substantial panel and very good appointments. Excellent scope for major surgery. Suitable house available. Premium 2 years purchase.

The Agency has made arrangements for special facilities on very favourable terms to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Valentine's Meat-Juice

In Typhoid Fever, Diarrhoea and Cholera Infantum, when it is Essential to Sustain the patient without irritating the Digestive Organs, the Ease of Assimilation and Power of Valentine's Meat-Juice to Restore and Strengthen has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste ease of administration and entire assimilation recommend it to physician and patient

Please are invited to send for brochures containing clinical reports

LONDON

BRITISH MEDICAL ASSOCIATION

1 AVISTOCK SQUARE

Formula

Intestinal glands -	- 0 0 5	grms.
Biliary extract -	- 0 10	"
Lactic ferments -	- 0 05	"
Agar-agar -	- 0 05	"
Fiat tablet -	- 0 35	"

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays must have two essential characteristics

- 1 They must be biological i.e., they must accord with and imitate in their action the natural physiological processes of the intestine
- 2 They must be capable of educating the intestine so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained

Taxol has both these advantages

Taxol has not the violent irritant action of many laxatives and purgatives but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle and does not force the weakened intestine to efforts beyond its power which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation after a course of TAXOL, revert to normal and regular peristalsis.

Telephone Royal 2121

It's no advertising humbug to say that Aertex Cellular underwear is healthier, it's just common sense. Everyone knows the story of the gilded child in the papal procession dying in convulsions due to suffocation, the body breathes through the pores and obviously an underwear woven into millions of tiny air-cells protects and insulates its wearer against extremes of heat or cold, keeps him or her fresh and cool in muggy weather and generally helps to avoid chills. Complete 1937 catalogue gladly sent on request.

MAKE THIS TEST

BEFORE YOU BUY SURGEONS' GLOVES

● Inflate the end of a finger as fully as possible. Then look for telltale rubber "drip" mark at the tip of the finger! You'll find none in Seamless Standard Latex Surgeons' Gloves, for they are uniformly thin, yet tough throughout—moulded to the hand. No excess rubber anywhere, free from thickened spots or imperfections that dull your touch.

The "gloveless" feel of Seamless Standard Latex Surgeons' Gloves is further emphasized

by the accuracy of their anatomical design. They do not bind or resist. They co-operate with every move of your hands.

Try on a pair, wet them, and note the secure and firm grip which you have on your instrument. See how well they fit and feel. Seamless Standard Latex Surgeons' Gloves are made for their job and do it well. Made by the manufacturers of the famous *Moderati* Surgeons' Gloves, unequalled at their price.

'CELLANBAND' ANTISEPTIC PASTE IMPREGNATED BANDAGES

The CELLANBAND Dressing when properly applied furnishes a mechanical support vastly superior to crepe or rubber bandage, elastic hoary, etc., and will usually be found sufficiently robust to enable the convalescent to resume reasonable light duties at an earlier period. CELLANBAND Dressings exercise a marked dehydrating and antiphlogistic effect resulting in rapid reduction of oedema. Air access to the tissues is not interfered with as in the case of occlusive dressings, so that evaporation of the skin secretions continues normally.

12/- PER DOZ (7 yds long 4 in wide)
SAMPLE BANDAGE 1/- POST FREE

'SANOID' STERILIZED LIGATURES

These ligatures are British both in production and materials. Their Tensile strength is well in excess of the recognised standards for particular sizes. A special process gives a surface finish that ensures easy manipulation. SANOID Ligatures are exceedingly supple, the catgut straightens out and remains straight without kinks which are liable to cause breakage. Sterilization is carried out by the most up-to-date methods and independent bacteriological tests over several months in all cases gave negative results. Exceptional elasticity lessens the risk of necrosis.

FOR ACIDOSIS

Not until you have used Alka-Zane will you know how effective alkaline treatment can be. Alka-Zane contains the four bases, sodium, potassium, calcium and magnesium, of which the alkali reserve of the body is essentially composed. These are present in Alka-Zane in the form of carbonates, citrates and phosphates. No tartrates, lactates or sulphates, no sodium chloride. A granular effervescent salt, that makes a zestful, palatable, refreshing drink, such is Alka-Zane. It is supplied in 4-ounce bottles. A teaspoonful in a glass of water is the dose.

8, 40 & 80 oz Bottles

IDOZAN meets the fundamental requirements of an effective iron therapy. It establishes a strong positive iron balance. It is easily absorbed from the intestinal canal providing a ready and abundant storing of surplus iron. IDOZAN is non-constipating, non-irritating and does not discolour the teeth.

Valentine's Meat-Juice

FOR Quieting the Irritable Stomach
and Aiding the Tired Digestive
Organs, for Refreshing the Fever
Patient and for Restoring and
Strengthening when Other Food
Fails, Valentine's Meat-Juice is used
in Hospitals and prescribed by many
leading Physicians and Surgeons

*Physicians are invited to send for Clinical Reports from
Hospitals and General Practitioners in all parts of the world*

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY
RICHMOND, VIRGINIA, U.S.A.

"For a Tired Stomach"

To a high degree the important fresh-fruit constituents of ripe pineapple are in **THIS ORIGINAL PINEAPPLE JUICE FROM HAWAII**

We believe you as a doctor, interested in the welfare of your patients will insist on quality and goodness in every fruit juice that you may recommend. These facts, then, will interest you. Dole Hawaiian Pineapple Juice is the original Hawaiian pineapple juice. It has received the Seal of Acceptance of the American Medical Association's Committee on Foods. It is a natural source of vitamins A, B, and C. The exclusive Dole Fast Seal Vacuum Packing Process retains in high degree those important fresh fruit constituents which you want when prescribing a fruit juice to your patients.

J. K. Husband & Co., Ltd., 10 Eastcheap, London E.C.3

Here is a typical analysis of Dole Pineapple Juice

Moisture	85.30%
Ash	0.4
Fat (ether extract)	0.3
Protein (N x 6.25)	0.3
Crude fibre	0.02
Titratable acidity as citric acid	0.9
Reducing sugars as invert sugar	12.4
Carbohydrates other than sugars (by difference)	0.38

THE TORCH FISHERMAN—On still nights off Waikiki can be seen the flickering torches of Hawaiian fishermen. The glare from the fiery stick attracts the fish, and with one swift movement of his spear the fisherman has unspiced his breakfast.

P.S.

If you would like a free sample tin of delicious Dole Hawaiian Pineapple Juice—write us a line on your letterhead now and we will send you a sample tin at once, free.

CAFFEDRIN (DUNCAN)

Each fluid drachm contains
Caffein Iodid 5 grs
Ephedrin HCl $\frac{1}{8}$ gr
Inf Coffeae q s

Caffedrin (Duncan) is recommended as a Cardiac and Respiratory Tonic, and is indicated in cases of Asthma Chronic Bronchitis etc

ELIXIR EPHEDRINE (DUNCAN)

Each fluid drachm contains
Ephedrin Hydrochlor $\frac{1}{4}$ gr
Sodu Iodid 2 grs

A pleasantly flavoured preparation which has given good results in the treatment of Asthma Whooping-cough etc

WHOOPING COUGH

Detoxicated Whooping Cough Vaccine (Genatosan) has proved remarkably successful. Reports received from medical practitioners state that it usually reduces the frequency of the paroxysms after the first injection, and subsequent injections almost invariably clear up the condition. Owing to the elimination of the toxic elements of the germ during the process of manufacture, this vaccine may be given to infants and young children, in doses sufficiently large to produce the desired therapeutic effect, with an absence of harmful reaction.

The following is typical of many reports received from physicians —

"I have been making a somewhat extensive use of your Detoxicated Vaccine for Whooping Cough, and am pleased to say that the results have been almost invariably gratifying. In nearly all my cases the very distressing symptoms have disappeared after the third injection" — M D

Additional information regarding this Vaccine will gladly be supplied on request

COMFORT FOR HAY FEVER AND NASAL CATARRH PATIENTS

Quick relief from the severe paroxysms of hay fever can be obtained by the direct application of Endrine to the nares

The ephedrine content by its vaso-constrictive action exerts prompt control and the relief obtained is prolonged for some hours. The ephedrine used in Endrine is the natural product obtained from the Chinese plant Ma Huang (Ephedra Helvetica).

For small children and in adult cases where the mucous membrane is hypersensitive use Endrine Mild—a modified formula without menthol.

ALASIL

Safe Salicylate Therapy

THE popularity of acetyl salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non narcotic analgesics available. Too often, however, its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

"Alasil" provides the beneficial therapeutic effects of pure acetyl-salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl salicylate—the least irritating salicylate compound—with "Alocol" a potent gastric sedative and antacid.

Since "Alasil" is better tolerated than acetyl-salicylic acid its use can be pushed or prolonged to a much greater extent than the latter. "Alasil" is therefore an analgesic, antipyretic and antirheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

The importance of The Qualitative Adequacy of the Diet

" if the diet is unsuitable the body cannot be properly constructed neither can it function effectively

(Ministry of Health First Report of Advisory
Committee on Nutrition 1937 p. 6)

The report quoted above stresses the need for ensuring that the whole community is provided with food which is qualitatively adequate. And it is acknowledged that foodstuffs containing vitamins play an important role in the economy of the body. Marmite is a yeast extract

that is exceptionally rich in vitamin B₁ and the B₆ complex it is prescribed extensively for its positive health promoting properties. Marmite has many uses in preventive and curative medicine and there is ample evidence of the benefit accruing from its regular inclusion in the diet.

Continued Clinical Evidence

Evidence continues to accumulate as to the value of 'Pentnucleotide' in the treatment of certain blood dyscrasias. Imerman and Imerman, in reviewing the eight published cases of granulopenia following the administration of dinitrophenol, state —

"The five patients who received 'Pentnucleotide' recovered. One of the two patients who received adenine sulphate died. The one patient who received only liver extract and blood transfusions died. As our second patient promptly recovered from 'Pentnucleotide' alone, the value of other forms of therapy such as liver extract, X rays, leukocytic cream, leukocytic extract and blood transfusions are questionable."

(J.A.M.A., 106 1088 (March 28), 1936)

ANTOSTAB BRAND

Gonad Stimulating Hormone

Available for Clinical Use

ANTOSTAB—a new gonadotrophic hormone prepared from the serum of pregnant mares is now available for clinical use

ANTOSTAB is unsurpassed by any other known hormone for its follicle-maturing activity, and must not be confused with anterior-pituitary-like substances obtained from pregnancy urine which have a luteinising effect, and frequently do not stimulate the follicles of the ovaries to any extent. (Proc Roy Soc Med, 1937, 30, 267)

Although the full therapeutic possibilities of this new sex hormone have not yet been explored, excellent results have been obtained in the treatment of Primary and Secondary Amenorrhoea and Metrorrhagia

CASE REPORT

"A woman, age 28, stated that her last period occurred 10 years ago. On examination the uterus was very small, but after four injections of Antostab the uterus was definitely growing larger. Following four more injections she had a short period. Curettage was performed about the 22nd day of the following 'cycle' to obtain a piece of endometrium. This showed early secretion in the endometrial cells."

ANTOSTAB is supplied in boxes containing ampoules of 100 mouse units per ampoule, and ampoules containing 1 c.c. of 0.90% Sodium Chloride Solution as a solvent for Antostab. Single ampoules and boxes of six ampoules

"JUST LOOK AT THESE, SIR..."

Left —The indigestible casein clot formed by cow's milk with an equal bulk of plain water

Right —The finely divided precipitate formed when cow's milk is modified by Robinson's 'Patent' Barley

In infant feeding, unmodified cow's milk tends to form a tough casein clot and is thus liable to cause indigestion. The specimens shown above illustrate the results of an experiment made in our own Research laboratories. They are 'in vitro' reproductions of the 'in vivo' conditions prevailing in an infant's stomach, and they show that the formation of the indigestible clot can be prevented if cow's milk is modified by Robinson's 'Patent' Barley.

HOW
CADBURY'S MILK CHOCOLATE
MEETS A REAL NEED
FOR THE ORDINARY MAN AND WOMAN

Too long a gap between meals—and recent research has shown that the big conventional meals *are* too far apart—reduces efficiency and introduces an element of strain into everyday life

Some small but nourishing between-meal snack is markedly beneficial in every normal case—milk is an example of a food that perfectly fulfils the necessary conditions. Unfortunately, however, the conditions of their work prevent many men and women to-day from taking any save the most compact and portable forms of nourishment in these long between-meal gaps. It is here that Cadbury's Milk Chocolate, at once handy, nourishing and energising, proves of the greatest value. Where the consumption of liquid milk would be impracticable, Cadbury's Milk Chocolate supplies all its goodness in concentrated form.

A vitamin assay of samples of Cadbury's Milk Chocolate taken from current production and tested by the highest independent authority indicates that this chocolate contains 6 International Units of Vitamin A per gram as compared with a stated potency for milk of 3 International Units per gram.

It will thus be seen that the process by which milk is converted for use in Cadbury's Milk Chocolate results in the concentration of its goodness without the modification or loss of those qualities which make milk so valuable a food.

THE TREATMENT OF HAYFEVER

'POLLACCINE,' the vaccine prepared in the Laboratories of the Inoculation Department (Founder, Sir A E Wright, M D, FRS) of St Mary's Hospital, London, from the pollen of Timothy Grass, is useful not only for prophylactic purposes, but also for the relief of symptoms in hayfever patients who have not received prophylactic doses during the Spring or who have not been sufficiently desensitized. It must be borne in mind that during the hayfever season the patient is already receiving air-borne pollen and, consequently, only a small dose of the vaccine can be tolerated.

For symptomatic relief two preparations which may be applied to the nasal mucosa are ANESTHONE CREAM and ADREPHINE INHALANT.

ANESTHONE CREAM contains benzocaine, Adrenalin Chloride and ephedrine hydrochloride in a base compound of lanolin and petrolatum, a small quantity may be applied to the nasal mucosa and the conjunctiva every two or three hours if necessary.

ADREPHINE INHALANT contains these three ingredients in a fluid medium suitable for application as a nebula from a 'Glaseptic' Nebulizer.

Further details will be furnished on request

ANAHÆMIN B.D.H.

In Pernicious Anæmia

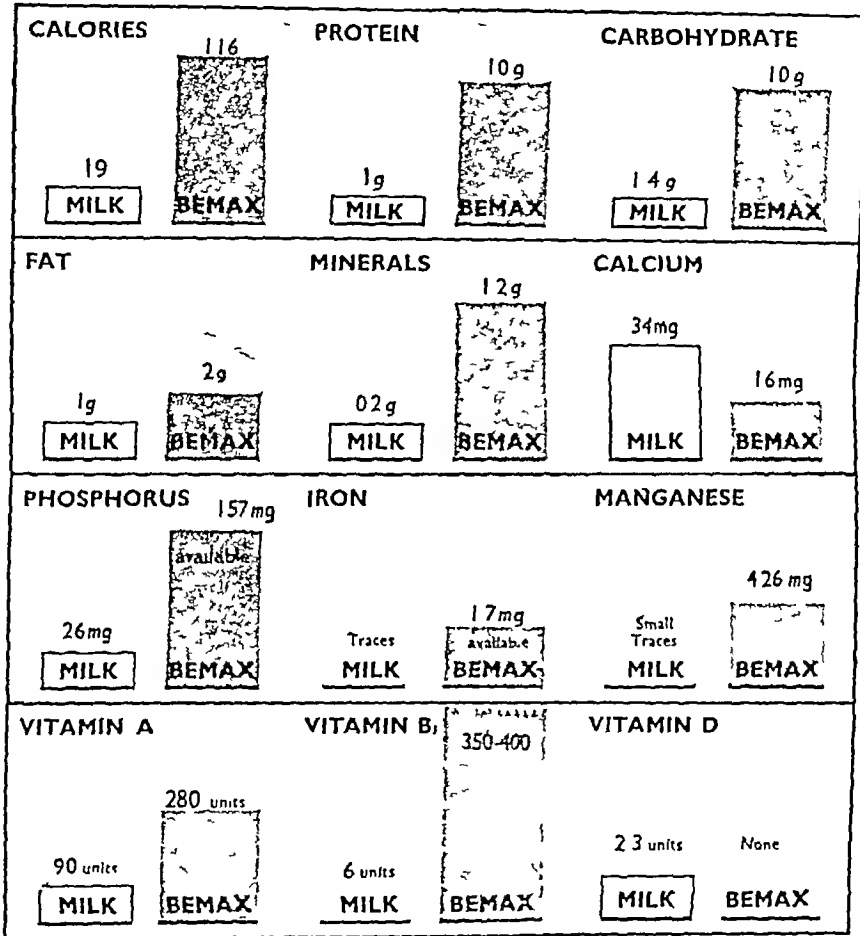

Anahæmin B D H presents in a high degree of purity the active hæmatopoietic principle of liver which has been separated from the reaction-producing protein substances. Although the constitution of anahæmin is not yet elucidated, its characteristics are sufficiently well-known and standardised to ensure the issue of a product which is unvarying in chemical composition as well as in anti-anæmic potency.

The uniform therapeutic activity of Anahæmin B D H is guaranteed by clinical tests upon actual pernicious anæmia cases, and, in addition, every batch is required before issue to pass stringent biological, chemical, physical and bacteriological tests.

THE BRITISH DRUG HOUSES LTD. LONDON N 1

Two valuable foods compared

The figures are for quantities of 1 oz. each of Milk and Bemax

That the Vitamin B₁ content of Bemax is 60 times that of milk is probably not surprising, but the fact that its caloric value is 5 times greater than milk, and its protein and carbohydrate content ten times as high (to quote only three examples from the above charts), emphasises the high all-round nutritional and therapeutic value of this natural Vitamin tonic food. Special importance probably attaches to the high IRON content of Bemax.

Laboratory reports on Bemax and a clinical sample for personal trial sent on request

Cystopurin

The ideal urinary antiseptic for oral administration!

- | | |
|--|---|
| 1 Produces no gastric irritation or toxic symptoms | 5 Acts from the renal pelvis downwards |
| 2 Is readily absorbed from the gut and excreted in the urine | 6 Is active in either acid or alkaline urine |
| 3 Causes no renal irritation | 7 Perfectly safe for use in febrile conditions |
| 4 Renders the urine bactericidal in low concentrations | 8 Acts on all causative organisms of urinary infections |

HAEMATURIA

From information received:—

"I had a patient suffering from haematuria following influenza. I treated him with Cystopurin, and the condition cleared up almost like magic"

I had a patient with severe haematuria which I put down to calculi in the bladder. I at first considered the idea of sending him to hospital and having the stone removed as he was getting very weak through loss of blood. Then I put him on Cystopurin, and found almost immediately relief. The symptoms gradually subsided and he is now quite well. The one great advantage in it, above all other drugs, is that IT CAN BE USED WHETHER URINE IS ACID OR ALKALINE."

"I have used Cystopurin in a case of haematuria, and the patient having derived so much benefit, is now using it regularly"

"I administered Cystopurin in a case of haematuria and B. coli infection in a male aged 63 years. Micturition was painful, scalding, scanty and frequent, pulse 108 and temperature spiky being highest in the evening. This was a case where a chronic cystitis had lighted up again and the bladder wall had thickened, some of the trouble being due to prostate. I gave six Cystopurin tablets in 24 hours during the first week, then three, and after 14 days treatment, pulse and temperature became normal and patient looked very much better."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

First cure the constipation . . .

The dangers of constipation are doubtless occasionally overstressed, but they are far more often under-estimated. Opinions based on centuries of experience are rarely without foundation, even though the rationalised explanations offered turn out to be fallacious. It was almost habitual with doctors, during what we may call the empiric ages of medicine, when, dealing with almost every form of illness, to ensure, first of all, that the bowels were acting regularly and adequately.

"First cure the constipation" is among the classic medical aphorisms that live. It is common experience that a very large proportion of so-called minor illness is associated with some degree of eliminatory sluggishness. When this is remedied, we are often surprised at the speedy disappearance of unpleasant symptoms seemingly remote.

The harm that may be caused by the drastic purges and the irritant aperient drugs favoured by last century practitioners is now generally recognised. What is desired is a preparation that will gently promote peristalsis by the same agency as that which, in health, naturally operates. It is suggested that ENO fulfils this requirement. It is a carefully compounded mixture of fruit-acids with alkalis. It has no ingredient irritative to the nerve-endings of the intestinal lining, its action being due entirely to its capacity for retaining fluid within the alimentary canal, through the principle of osmosis. The slightly increased tension thus caused is both painless and harmless, being, in fact, the natural provocant of intestinal activity.

ENO's Fruit Salt consists of fine granules which when dropped into a glass of water dissolve instantly and uniformly with sparkling and refreshing effervescence.

ENO'S 'FRUIT SALT'

The Words 'Eno' and 'Fruit Salt' are registered trademarks

BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 29 1937

PATHOGENESIS OF ECLAMPSIA

81

W. R. ADDIS, M.C., M.B., Ch.B. Ed., F.C.O.G.

Honorary Gynaecologist Salford Royal Hospital Honorary Assistant Surgeon for Women St Mary's Hospitals Manchester

The subject of eclampsia has become so overgrown with fact and theory that at times one as a clinician feels in danger of losing sight of the wood in consideration of the trees. I therefore offer no apology for the following attempt to reduce eclampsia to the form of a diagram.

Acute Glomerulonephritis and Eclampsia

The resemblance between acute glomerulonephritis and eclampsia in symptoms and morphological change is so close that one might reasonably expect some similarity in pathogenesis in spite of their aetiological difference. In both we find albuminuria, oliguria with a high specific gravity and absence of retention in the blood of urinary constituents. The morphological change in the kidneys in the two diseases differs in degree rather than in kind. Both are hypertensive conditions and hypertensive encephalopathy, the characteristic symptom of eclampsia, is also apt to occur in acute nephritis. Both show oedema and though in one there is a typical liver lesion absent in the other this discrepancy one would suggest may depend on a difference in aetiology rather than pathogenesis. Although in acute glomerulonephritis pre-eclampsia and eclampsia the renal lesion is only one manifestation of a generalized reaction the kidney is so widely employed both clinically and in experimental work as an indicator that one or two generally accepted facts having a special

serum with all its soluble contents, except serum globulin and serum albumin, which have too large a molecule to pass through uninjured endothelium is transferred to the cavity of Bowman's capsule and thence into the tubule.

That the tubule has an active function is shown by the high oxygen consumption of the kidney. Its function is one of selective reabsorption from or concentration of the filtrate, thus sugar is completely reabsorbed, water according to the need of the body and salt sufficient to maintain the pH of the blood. The non-threshold substances such as urea pass with the excess water into the collecting tubules and so out as urine. For our present purpose then the term renal function refers solely to the action of the tubule.

The Kidney in Acute Glomerulonephritis

Let us take as our starting point the morphological change found in the kidney in acute glomerulonephritis. This is almost entirely confined to the glomerular capillaries and the afferent vas. Apart from an occasional slight cloudy swelling at the proximal end of the tube the tubules show no change as one would expect in view of the high specific gravity of the urine (1030) and the absence of retention of urinary constituents in the blood. Where such a retention might be expected from a fall in the excretion of urea with a drop in filtration to below an amount sufficient to deal with the total urea production of the body, the fact that an abnormally high blood urea is not as a rule found is explained by the power of the anasarca fluid to store urea in about the same concentration as that in which it occurs in the blood. This may account for the high death rate in cases of eclampsia without oedema in which in effect a uraemic element however slight is superimposed.

The essential kidney lesion is dilatation of the afferent vas and glomerular capillaries with well marked ischaemia of the tuft. Bell in 1932 demonstrated a hyaline change in the basement membrane to explain the patency of the almost empty capillaries. (Shaw Dunn in 1934 demonstrated by means of Mallory's connective tissue stain a slight thickening of the basement membrane in the kidney of eclampsia and pre-eclampsia.) The endothelium is thickened and shows a slight tendency to proliferation. The epithelial layer reveals a similar change. A few leucocytes are present. The whole tuft is swollen and completely fills Bowman's capsule at times showing a tendency to herniate into the tubule. The glomerular capsule is universal not focal. The intertubular capillaries are dilated and engorged.

Pathogenesis of Acute Glomerulonephritis

There are two main theories as to the pathogenesis of acute glomerulonephritis. The first (which is ascribed by Fishberg to Conheim and Lichtheim, 1877) is based on the fact that the disease occurs in the course of acute infections, especially scarlet fever and tonsillitis. It describes the condition as one of generalized toxic injury to the capillaries, of which the kidney lesion is only one manifestation. This concept of the condition as generalized is supported by the fact that oedema sets in early, simultaneously with or even before the appearance of albuminuria, and by the high protein content of the anasarca fluid. The severity of the capillary change in the glomerulus, through which toxin is eliminated, as compared with that in the intertubular capillaries and those of other organs, was held to indicate its toxic origin.

Against this however, we find that injection into experimental animals of the toxin or endotoxin of the *Streptococcus scarlatinae* though it produces an inflammatory reaction, fails to produce the ischaemia of the tuft characteristic of acute glomerulonephritis. Further, 'post-scarlatinal glomerulonephritis becomes chronic in only an exceedingly small proportion of cases' (Fishberg). Many cases of chronic nephritis give no history of a previous acute attack, though a history of scarlet fever or of some less acute infection is frequently obtained. As was shown by Trask and Blake in 1924, moreover, the toxin of scarlatina can be demonstrated in the urine, and we know that albuminuria is a frequent symptom in acute infective fevers. It would seem probable that a slight inflammatory change occurs in a proportion of these cases some of which may later develop chronic nephritis. It does not therefore seem wholly unreasonable to ascribe the inflammatory part of the glomerular lesion in acute glomerulonephritis to the action of the toxin of the scarlet fever, etc. and regard it as in existence before the onset of the nephritis. The essential kidney lesion of acute glomerulonephritis as found post mortem one would suggest, is therefore confined to a universal dilatation of the vasa afferentia and capillaries of the tuft with ischaemia.

Volhard's Theory

In 1923 Volhard put forward another theory of the pathogenesis of acute glomerulonephritis. He suggested that it was the result of a generalized angiospasm producing capillary ischaemia. The endothelium of capillaries accustomed to a pressure of 120 mm Hg might reasonably be supposed to be highly susceptible to anoxaemia. It probably undergoes an albuminoid degeneration with the formation of a smaller protein molecule consequent swelling and increased permeability. The oliguria may result from decreased flow of blood through the tuft or from a fall in intracapillary pressure. Shaw Dunn has suggested that as the glomerular change is diffuse it is possible that instead of only one in three of the nephrons functioning at one time as occurs normally all three are working simultaneously. Each glomerulus in this way filters only a third of the blood it otherwise would. The length of the tubule remaining constant the filtrate in this circumstance may be regarded as passing over three times the usual length of concentrating epithelium.

Opponents of Volhard's theory ascribe the oliguria to impermeability of the tuft owing to inflammatory swelling. We find however that the lumina of the capillaries show a fixed patency and contain a few red blood corpuscles. We also find engorgement of the intertubular capillaries,

and though the presence of some obstruction due to endothelial thickening cannot be denied, Volhard has shown that the kidney can be transfused after death has relieved the arteriole spasm.

The Renal Lesion

Baird and Shaw Dunn (1933) assessed the position of the renal lesion in eclampsia and pre-eclampsia as lying midway between the normal and that of acute glomerulonephritis. They agree with Bell (1932) that 'a distinction can usually easily be made between the two conditions the distinction being the absence of leucocytes or tendency to cell proliferation in the glomerulus of eclampsia. As this part of the nephritic lesion, one has suggested, is due to the elimination through the tuft of the scarlatinal or other toxin, and as this excretion has as a rule ceased before the onset of the nephritis, we may I think, for our present purpose justly regard the kidney lesions in the two diseases as identical in kind.

Common Pathogenic Factors

The main object of this paper is to show that in angiospasm we have a common pathogenic factor underlying and uniting all the varying expressions of eclampsia. Believing as one does that acute glomerulonephritis is an angiospastic condition, and having indicated an essential morphological similarity between the kidney lesions in the two diseases let us consider whether the analogy can be carried further to include all the manifestations of both conditions.

The first common symptom is oedema. In both diseases it is of rapid onset. There is a difference in the severity and distribution of the swelling but in both the high protein content of the anasarca fluid shows it to be due to endothelial injury. There is, however, no clear indication as to the cause of this damage except on an analogy with the other symptoms of the diseases. On the other hand, the pallor of the skin typical of acute nephritis is almost certainly due to angiospasm, and Hinselmann (1924) observed in cases of eclampsia, by means of the capillary microscope, constantly recurring spasmodic contractions of the capillaries at the base of the finger-nail at times producing complete cessation of flow. Capillary circulation is controlled by the Rouget cells, a layer of unstriated muscle encircling the vessel wall reticulated to allow of transudation of fluid. To these sympathetic fibres can be traced. We know that these cells are absent in the lung and kidney, while in the liver lobule not only are they absent but even the endothelium is incomplete. Further Williams (1936) has shown that the intracranial capillaries have no sympathetic supply. Accordingly in these organs we must look further back than the capillary for the site of our angiospasm.

In the retina of both diseases a spastic condition of the arterioles can be observed producing indentation of the venules at arterio-venous crossings. In extreme cases oedema can occur of such severity as to cause separation of the retina.

The rise in blood pressure cannot be regarded as a reaction to obstruction to the renal circulation alone as in acute glomerulonephritis the pressure seldom exceeds 180 mm Hg whereas in eclampsia with a much less severe kidney change it at times reaches great heights. It is more reasonable to suppose this to be due to a generalized arteriole spasm. In eclampsia with a higher pressure reaction we get a correspondingly wider distribution of lesion referable to angiospasm.

Hypertensive Encephalopathy

In this consideration of the manifestations of acute glomerulonephritis and eclampsia as due to angiospasm there is one last common symptom to be taken into account—namely hypertensive encephalopathy. This term was introduced by Oppenheimer and Fishberg in 1928 to describe the condition which Volhard in 1918 designated pseudo uraemia to distinguish it from uraemia with which it had previously been confused. Uraemia as its name implies is dependent on the presence in the blood of an abnormally high non protein nitrogen. The condition is insidious in onset and is preceded by muscular weakness and wasting. Anorexia and diarrhoea occur and the skin is pale and dry and shows a yellowish brown discoloration. The urine is as a rule greatly diminished but of low specific gravity (1010) and the urea concentration in the blood is high indicating failure of renal function. Babinski's sign is absent.

In hypertensive encephalopathy on the other hand the onset is dramatic in its suddenness. Vaquez and Nobé court pointed out in 1897 that the essential feature in eclampsia was arterial hypertension showing a rapid rise just before or coincident with the onset of the seizures. The attacks start with a generalized tonic spasm which gives way to a clonic convulsion followed by coma. The pupils are dilated and react sluggishly. Babinski's sign can generally be elicited. The pressure of the cerebrospinal fluid is raised and often greatly increased. No indication of failure of renal function is found on examination of the urine and of the blood.

Hypertensive encephalopathy occurs in three conditions—eclampsia, lead poisoning and acute glomerulonephritis. All three are hypertensive and in all the seizures are epileptiform in character. In regard to lead poisoning Vaquez (1904) showed that the colic occurred with hypertension and was due to constriction of the mesenteric vessels. Similarly the arteriosclerosis of chronic lead poisoning is held to result from spasm of the media. The spastic nature of the condition is further indicated by the pallor of the skin even in cases where the anaemia is slight and by the cramps which are a typical feature of the condition.

ample histological evidence the existence of an extensive sympathetic supply to the cerebral vessels with the exception of the capillaries. His final conclusion is as follows.

The sympathetic innervation of the intracranial circulation does not differ materially from that of the systemic circulation. It does not seem reasonable to suppose vessels with a full and normal sympathetic innervation incapable of contraction. If then we accept the possibility of intracranial angiospasm this would seem to be the simplest explanation of the cerebral ischaemia, with or without oedema which we find post mortem in all three types of hypertensive encephalopathy, more especially as in all three angiospasm can be demonstrated as occurring elsewhere at the same time. Lastly the presence of Babinski's sign absent in the irritative seizures of uraemia, indicates a cutting off of cortical control by ischaemia which it would be difficult to explain by any other mechanism in such a condition as eclampsia.

The Liver Lesion

Though the liver lesion of eclampsia does not occur in acute glomerulonephritis there would seem to be as much reason to consider it as due to an arteriole spasm with capillary ischaemia as is the glomerular lesion of both diseases. The essential liver lesion in eclampsia is a periportal haemorrhagic necrosis with a similar though naturally less marked change in the intracapsular tissue. The hepatic artery supplies the connective tissue in Glisson's capsule and the sinusoids of the area of lobule surrounding the capsule. It contributes one-quarter of the blood supply to the lobule and 40 per cent of the oxygen the main central portion being oxygenated by the portal veins (Starling).

The liver lesion has all the characters of a severe multiple infarction. It is confined to those areas of the lobule supplied by the hepatic arteries—that is, the only areas where angiospasm could produce ischaemia. Barcroft has pointed out the special liability of liver cells to injury from deprivation of oxygen which explains the severity of the lesion here as compared with the results of angiospastic ischaemia in other organs. In toxic conditions such as acute yellow atrophy the necrosis starts centrally and does not resemble an infarct. Were the eclamptic lesion due to cell injury by some toxic substance circulating in the blood it would be difficult in view of the open nature of the sinusoids into which the capillaries open to understand the strict localization of the lesion in uncomplicated cases to the periportal areas at the periphery of the lobule. I would then suggest that there is good reason to regard the hepatic lesion in eclampsia as a multiple infarction due to angiospasm of the hepatic arteries or their arterioles.

Other Manifestations of Eclampsia

There are many manifestations of eclampsia which have not been mentioned—for instance oedema of the lungs. This I had in mind when the absence of Rouget cells in his situation was mentioned. Ischaemic injury to the alveolar capillaries from intermittent spasm of the pulmonary arteries would be expected to result in oedema and congestion. This is also accentuated by cardiac failure the termination of many fatal cases. It has been said that each fit brings the patient nearer her end. I think that the number of fits is of great prognostic value. I would have been probable that the fits of them

selves could lead to a fatal termination it is rather that the seizure is the outward and visible sign of a sudden access of angiospasm, which must affect the myocardium just as it affects practically all the tissues of the body

Lastly there is one other symptom of grave prognostic value which deserves mention—namely, a rise in temperature. This may in part be due to decreased loss of heat during the exertion of the seizures by spasm of the superficial capillaries. This alone would however, be a completely inadequate explanation. Pyrexia, one would suggest, is the expression of an exceptionally severe angiospasm. In anaesthesia the first things to go are consciousness and the power of voluntary movement. As the anaesthesia advances it spreads downwards and gradually affects the lower centres in the pons and medulla, ultimately causing death. So with ischaemia a moderate degree will knock out the higher, cerebral, portion of the brain while the lower centres remain comparatively unaffected. Only a very severe angiospasm will suffice to affect the heat-regulating centre in the corpus striatum. *It is not surprising that the prognosis in such a case is grave*

Commentary

It would be impossible in the space of a short paper to cover the infinite variations of such a disease as eclampsia. All one can hope to do is to include what are considered to be essential features alone. I have merely attempted to draw a diagram. Such a diagram I conceive as having at its centre angiospasm. This spreads out into various tissues and organs producing effects which in themselves appear to be completely unrelated. In the brain it results in hypertensive encephalopathy, in the kidney, albuminuria and oliguria with a high specific gravity, in the liver, a periportal necrosis, in the subcutaneous tissues, anasarca and in the skin, though it is frequently masked by deficient oxygenation of the blood, pallor. I would suggest that these variations are the result not of a varying cause but of the variety of tissues in which it acts, and that there is one single pathogenic factor underlying and uniting all the manifestations of eclampsia—namely, angiospasm.

The fourth annual report of the Research Institute and the Endemic Diseases Hospital, published by the Ministry of Public Health, Egypt, deals with the year 1934. During this period an investigation of the chemical composition of the spleen in Egyptian splenomegaly was initiated and the results of analysis will be given in a subsequent report. The urine of 116 adult females attending child welfare centres in Cairo was examined for bilharzial infection which was discovered in forty-four cases. Nine of these women had never left Cairo. Further inquiry showed that eight of the nine lived in suburban districts where filtered water was not available. *Buhinus* snails were discovered in the streams from which these women drew their water supply although no cercariae were to be found. Schistosoma infection was very high in those parts of the country where systems of continuous irrigation have been introduced the percentage reaching 75 in some districts. In the clinical section of the report it is stated that founadin is used for the routine treatment of schistosomiasis. Examination of the urine of 11,635 outpatients demonstrated the presence of ova of *Schistosoma haematobium* in 45.7 per cent, and stools contained the ova of *Ankylostoma duodenale*, *Ascaris lumbricoides* and *Trichostrongylus* in 28.2, 16.8 and 12.8 per cent of cases respectively. Ankylostomiasis is treated by carbon tetrachloride with satisfactory results.

INTERMITTENT VENOUS OCCLUSION IN THE TREATMENT OF OBLITERATIVE VASCULAR DISEASE

BY

J. J. MASON BROWN, M.B., F.R.C.S. Ed.

*Assistant Surgeon Royal Hospital for Sick Children
Edinburgh*

AND

W. MELVILLE ARNOTT, M.B., B.Sc. M.R.C.P. Ed.

*Lecturer in Therapeutics University of Edinburgh
(From the Laboratories of Clinical Medicine and Clinical
Surgery Royal Infirmary, Edinburgh)*

Obliterative vascular disease with its inevitable sequelae of intolerable pain and progressive gangrene, provides one of the most baffling and melancholy problems in both medical and surgical practice. It is especially tragic in the young or middle aged patient with thromboangitis obliterans in whom amputation of one or more limbs is a common event. It is clear therefore that any method of treatment which holds out a prospect of improvement in the peripheral circulation merits attention. Division of the sympathetic nerve supply in such cases can only increase the blood supply in so far as the obstruction is due to associated vasospasm. In those cases in which obliterative organic disease is the dominant factor in the obstruction it is obvious that some other line of therapy must be employed.

Lewis and Grant (1925) in a study of reactive hyperaemia in man found that when the arterial supply to a limb was occluded there resulted a state of vasodilatation lasting from half to three quarters of the period of circulatory arrest. This dilatation involved both the superficial and deep vessels of the limb and was independent of the central nervous system and local reflexes. An exactly comparable reaction followed increase of venous pressure in a limb. It was apparent at as low a cuff pressure as 40 mm. Hg, and became more pronounced up to the point of occlusion of arterial flow. They concluded that the vasodilatation affected the capillaries and smaller arterioles only and was caused by the accumulation in the extravascular tissue fluids of slowly diffusible substances produced during the period of circulatory disturbance. Very recently Barsoum and Smirk (1936) have studied venous blood from limbs in a state of reactive hyperaemia. They found an increase in the concentration of a substance which resembled histamine in its biological properties.

The Apparatus

From a consideration of Lewis and Grant's work Collens and Wilensky (1936a) devised an apparatus which raised the pressure in a cuff encircling the limb to any desired pressure in cycles of two minutes pressure followed by two minutes release, and in a more recent paper (1936b) have reported the result of the treatment of a small series of cases of obliterative vascular disease by this method. The results were strikingly successful, pain being almost immediately relieved, ulcers healed and gangrene averted. We have had an apparatus constructed for this purpose and it has now been in use since the beginning of February. We had intended to observe the results of this treatment in a large series of cases before publication but the editorial appeal in the March 6 issue of the *British Medical Journal* for the production of a simple apparatus for this form of therapy indicated that a description of our apparatus might be of interest. It is simpler in construction than that devised by Collens and Wilensky.

The apparatus was designed and manufactured in three forms for us by Mr T W Forbes of the Chalmers Edison Company of Engineers, Leith. The original apparatus which is illustrated consists of a reciprocating air pump driven by a constant speed electric motor. The motor is fitted with a reducing gear driving a cam revolving once in four minutes. The cam actuates the valves connecting the pump and the cuff so as to provide two minutes pressure and two minutes rest. A mercury manometer indicates the air pressure which is regulated by an adjustable valve. As the apparatus has to be in operation for long periods a series of coloured lamps have been incorporated. These indicate (a) when the machine is in operation (b) when there is no pressure in the cuff and (c) the elevation of the pressure to more than 10 mm Hg above the predetermined pressure.

Fig. 1. Diagram of the original apparatus. For the sake of clarity the wiring and the signal lights have been omitted.

The apparatus in its second form is such that it can

intensely painful. Arterial pulsation was absent below the knee on palpation. Oscillometry in the middle third of the leg gave a maximum reading of 2.5 on the left side and 6.5 on the right side. No readings could be obtained at the level of the ankle on the left side whereas on the right side the reading was 2.8 at this level.

Treatment by intermittent venous occlusion was instituted and resulted in a dramatic relief of pain. An average cuff pressure of 50 mm Hg was employed. The duration of application was approximately ten hours a day. After a total of ninety hours' treatment the patient was able to walk a distance of one mile without pain. The duration of treatment was gradually reduced until now one hour's treatment daily is sufficient to allow him to lead a normal life. A chilblain which had been present for months and had been acutely painful became painless and healed rapidly. The only un-

Chart 1 showing oscillometric readings before and after treatment. (1) Reading at junction of upper and middle thirds of leg after treatment. (2) Reading at same level before treatment. (3) Reading at level of ankle after treatment. No reading could be obtained at this level before treatment.

areas and increased oscillometric and surface temperature readings

We are indebted to Professors Sir John Fraser and D M Dunlop for the facilities of their respective departments and for their continued advice and interest, and our thanks are due to Mr T W Forbes for the design and construction of the apparatus. We are also indebted to the Earl of Moray Endowment for a grant towards the expenses.

INCIDENCE OF SYPHILIS AMONG SCHOOL CHILDREN OF KINGSTON, JAMAICA*

BY

DAHLIA WHITBOURNE, M B, B S Lond

AND

GEORGE M SAUNDERS, B.A, M D Harvard

The impression is given in a report (Neville Rolfe, 1936) recently submitted to the Government of Jamaica that syphilis is particularly prevalent in the general population among both adults and children. The report, however, was based upon observations made largely in hospitals and almshouses among the sick and more unfortunate classes, in which a high incidence of syphilis does not necessarily indicate a similar condition for the entire population. Other studies based upon observations of unselected samples of the population have not been recorded. It was felt, therefore, that a serological survey would be highly desirable as a means of estimating the true incidence of syphilis.

Source of Material and Technical Methods

Pending investigations among adults a serological survey of school children was undertaken. Children were selected at random from those in attendance on an ordinary school day at seventeen schools which serve the majority of the lower middle and lower classes of Kingston, practically all of whom are black or coloured. The method of selection was to have the teachers choose indiscriminately volunteers to submit to a blood test the nature of which was unknown to the children. It is felt that this system gave a random sample which possibly erred on the side of selecting the less healthy individuals. Each child was examined by one of us and blood specimens were taken. Nearly every child whose blood gave positive serological tests was brought to a hospital clinic, where more careful examinations were conducted than was possible at the time of the first visit. Also repeated tests were made on fresh samples of all blood sera which gave positive or questionable results.

Note was taken of any signs of congenital syphilis or yaws, and particular inquiry was made for a history of yaws or injection treatments. It is well known that yaws, which gives positive results with routine serological tests as consistently as syphilis, is prevalent among the children of rural Jamaica many of whom come into Kingston and enter school. For this reason great care was taken to secure accurate information about a previous yaws infection and any history of this disease was carefully checked.

* The studies upon which this report is based were conducted with the support and under the auspices of the International Health Division of the Rockefeller Foundation and the Government of Jamaica.

with parents or guardians. No case was classed as yaws unless there was a definite clear cut story of infection for which injection treatments had been given, and if a child had not lived at some time in an area where yaws was known to be endemic a positive history was discredited unless characteristic scarring or active lesions were present. It has been shown (Turner and Saunders 1935) that a history of yaws infection as given by children or parents is highly accurate, but that a negative history is more subject to error.

There were 1,103 children examined of whom 504 were males and 599 were females. The ages varied from 5 to 16 years, but the great majority were between 10 and 14 years old (Table I). Racially they were practically all black or coloured, there being very few Chinese, East Indians, and whites (Table II).

TABLE I—Age and Sex of Children Examined

Age in Years	Males	Females	Total
5—9	138	103	241
10—14	364	485	849
15—16	2	11	13
	504	599	1 103

TABLE II—Race and Sex of Children Examined

Race	Males	Females	Total
Black	275	272	547
Coloured	214	304	518
East Indians	5	2	7
Chinese	6	16	22
White	4	5	9
	504	599	1 103

All sera were examined in the laboratory of the Jamaica Yaws Commission, where the Wassermann and Eagle tests were performed on each. The Wassermann complement fixation reaction was a standard modification in which the antigen consisted of a cholesterolized alcoholic extract of beef heart, and the preliminary incubation was carried out in the refrigerator (5 C) followed by half an hour of incubation in the water bath at 37 C. The standard Eagle flocculation test was used, except that the serum antigen mixture was allowed to stand at room temperature (26 to 28 C) for twenty-four hours before adding saline and reading the results. Five years of experience with the methods used had proved them to be highly sensitive and specific. In addition 600 bloods were subjected to the Kahn test at the Government laboratory through the kindness of the pathologist, Dr K Leigh Evans. The results of the Kahn test were practically identical with those of the Eagle test.

Results of Study

Serological Tests—In forty three children, or 3.9 per cent, the serological tests were positive. Both Wassermann and Eagle tests were positive in forty, Wassermann partly positive Eagle positive in two, and in only one instance was the Wassermann negative and Eagle positive to repeated tests. But there were thirteen children among the positive group who gave a clear-cut history of yaws and whose positive tests were almost surely the result of the yaws infection. The remaining thirty children, or 2.7 per cent of the series had positive tests presumably because of congenital syphilis, the percentage being slightly higher among females than among males (Table III).

Clinical Findings—Signs of congenital syphilis were infrequent and none of the children with negative serological tests presented any definite findings although a few of them had slight enlargement of frontal bones or bowing of tibiae. Among the group with positive blood tests probably due to syphilis were ten with characteristic

lower classes of society, were examined clinically and serologically to determine the incidence of syphilis

2 There were forty three children or 3.9 per cent., giving positive serological reactions. Among these were thirteen whose positive reactions were almost surely due to yaws, leaving thirty, or 2.7 per cent, with probable congenital syphilis

3 It is estimated that congenital syphilis is present in about 3 per cent of all black and coloured children of Kingston

4 Syphilis doubtless reaches a much higher incidence among the entire population. The exact figure cannot be stated, but on the basis of evidence gathered elsewhere concerning the ratio of the incidence of syphilis in children to that for the entire population it may be said to be approximately 12 per cent

EPIDEMIOLOGY OF EPIDEMIC DROPSY*

BY

R B LAL, MB, BS, DPH, DTM & H, DB

Officiating Director

AND

S C ROY, MB, DPH, Capt ITC.

Assistant Research Worker All India Institute of Hygiene and Public Health Calcutta

Epidemic dropsy belongs to the group of obscure diseases, like tularaemia, which are little known outside their endemic homes. None the less this disease is of much interest to students of tropical medicine, and particularly to those of us who work in this part of the world. It is by no means a minor problem in the provinces of Assam, Bengal, Bihar, and Orissa. One would, perhaps, not be far wrong in saying that a practitioner in Calcutta comes across epidemic dropsy as frequently as malaria, if not more frequently. The city according to Mazumdar (1933), recorded deaths from epidemic dropsy every year between 1905 and 1931. Widespread epidemics involving thousands of citizens and causing heavy mortality occasionally occur. The epidemics in 1909, 1926 and 1927 were particularly disastrous when 433, 939, and 636 persons respectively are said to have died. Ten times this number must have been the victims of more or less permanent damage to the heart. The disease is not confined to the towns. Outbreaks occur even in the smallest villages and at times large tracts of country in the eastern provinces of Assam, Bengal, Orissa and Bihar become involved. Outside these provinces localized outbreaks have been reported from the eastern districts of United Provinces and parts of Madras Presidency. A few epidemics have occurred in

Burma, Fiji, Mauritius and certain other parts of the world but the disease has been practically confined to emigrants from those provinces.

Earlier Studies

The history of the disease carries us as far back as reliable records are available. Chambers (1880) believed that the disease had been prevalent since the famine of 1866. Good descriptions of epidemics occurring in the last quarter of the nineteenth century and since then are given by O'Brien (1879), Caley (1878), Payne (1879), McConnell (1879), Cronbie (1879), Deakin (1880), Kastagir (1880), McLeod (1893), Rogers (1902), Munro (1903), Cambell (1908), Greig (1911) and many others. How these epidemics arise, what factors favour their continuance and decline, how and why the disease prevalence is maintained at a low endemic level in certain localities, why certain communities suffer more than others, what determines the sex, age and occupational distributions, what preventive measures can be taken are some of the problems which have so far defied solution. In epidemic dropsy, as in many other diseases, bad weather, personal diathesis, water, inadequate or unsuitable food, unknown toxic substances, various types of organisms and even insects have received their share of blame at the hands of various workers. Yet the lack of exact knowledge cannot be said to be due to want of interest on the part of the profession. Among others epidemic dropsy has engaged the serious attention of eminent workers like Rogers (1902), Lukis (1908), Greig (1912), Megaw (1927), Acton and Chopra (1925) and many important contributions have been made. However, in the absence of exact knowledge every practitioner has perhaps either formulated his own theory or has adopted one advanced by others. We cannot do better than sum up the present position in the words of the editor of the *Indian Medical Gazette* (1935) when he says: 'Many theories regarding the cause of the disease have been formulated, have lived their day and become history, and have been revived again'. However, from amongst a multitude of theories three have received considerable support. These are (1) rice theory, (2) contagion theory, and (3) mustard oil theory. We propose to revive one of these theories and present fresh evidence in support of it, in the hope that it will stand critical examination and will not be cast away again into limbo.

Observations in the Field

These three theories formed our working hypotheses and it was mainly on these premises that we proceeded to collect exact information in the field. Investigations were made in seven different localities where epidemic dropsy was raging. These included rural, semi-rural and industrial areas in Bihar, Bengal, Assam and Orissa thus representing different living conditions. House-to-house visits were made and important data were collected on printed schedules specially designed for mechanical tabulation. In three localities data were collected for every individual and for each family, whether stricken or not. In other places investigations were confined to the affected families and to such unaffected families as were of special interest. Reasonable precautions were taken to ensure the veracity of the information recorded. Detailed information was obtained from 964 patients and 2,581 healthy persons comprising 310 affected families and 290 unaffected families. In addition certain relevant data were collected from 1,727 unaffected families having 9,676 members. The main points that emerged after critical analysis were:

* A more detailed description of these studies will appear in a series of five papers in the July 1937 issue of the *Indian Journal of Medical Research*.

which totals about 100 000, is very cosmopolitan Jamshedpur had been free from epidemic dropsy for some years when, in October, 1936, the first case occurred. Within five weeks 222 cases were reported, involving sixty-six families. Of these fifty-two were Bengalee families living on the usual Bengalee diet. The non-Bengalee victims were also found to have taken to Bengalee diet, at any rate rice and mustard oil were used by them in considerable quantities. The most remarkable feature of this epidemic was that the affected families had a common source of mustard oil supply. Eighteen of them obtained one particular brand of oil direct from the mill, of whom fourteen received it in original sealed containers and four loose, and thirty five obtained it from the grocers. In ten instances the grocers stored this brand, but the customers had not specially asked for it. In the case of three families the evidence was not so clear. There were no cases among the large clientele of the other three mills which supplied mustard oil to the town. Another important point is that the cases only appeared amongst people who had purchased the oil during October and the first week of November. The suspected brand of oil had been quite popular for some time, and nothing untoward had happened previously. Thus the suggestion is that a particular consignment of oil of this brand was associated with the epidemic. It may be mentioned here that the manufacturers claimed that the oil was unadulterated and of good quality. The genuineness of the oil was confirmed by chemical analysis, kindly carried out for us by the Professor of Public Health Laboratory Practice on a sample collected from one of the affected families.

Thus we see that the field studies, laboratory investigations, and observations under controlled conditions so far described threw doubt on the validity of the "rice" and the 'contagion' theories. They gave, however, a definite lead in favour of the mustard oil hypothesis stated above. Since we were able to procure samples of oil in original containers from the affected families it was now possible to test this hypothesis by feeding human volunteers on the suspected oil under strictly controlled conditions.

Feeding Experiments on Human Volunteers

The results of these experiments are very striking. It is not proposed, to go into the details of the experiments, but a few interesting facts are stated below.

Three experiments were performed, in each of which twelve healthy young subjects who were willing to take the risk and who were ready to give an undertaking that they would continue on the special diet for the required period were selected. In the first two experiments the subjects were divided into four groups of three each, and the experiments were arranged as below.

- Group A diseased rice and suspected mustard oil
- Group B "diseased" rice and *jail* produced mustard oil
- Group C clear rice and suspected mustard oil
- Group D clear rice and *jail* produced mustard oil

The main difference in the two experiments was the source from which the suspected oil was obtained. The oil used in Experiment I was collected from an affected family in Assam, while that used in Experiment II was obtained from an affected family at Jamshedpur. No untoward symptoms developed in any volunteer in the first experiment except in one of those taking suspected oil. He complained of loss of appetite and constipation. Later he developed a cold with slight rise of temperature but was restored to normal condition after a few days of rest and milk diet. In the second experiment, on the

fifth day after the commencement of the special diet, two persons in Group A and one in Group C missed their morning meal and all members of Groups A and C complained of pain in the joints and of symptoms of gastrointestinal disturbance. Later some of them developed fever and three developed oedema of legs with flush and pitting on pressure, which are characteristic of epidemic dropsy. Two of the oedema cases belonged to Group A and one to Group C. The last mentioned patient was taken out of consideration, because on closer examination he showed evidence of chronic filariasis. All the controls remained perfectly healthy and cheerful. That was the first occasion on which it had been possible to reproduce signs and symptoms of epidemic dropsy in human subjects. The value of these results is further enhanced on account of the history behind the suspected oil which was employed in this experiment.

However, it remained undecided whether oil alone could produce the condition or if it was necessary to combine "diseased" rice with it. A third experiment was therefore carried out in which "diseased" rice was excluded. The source of suspected mustard oil was the same as in the last experiment. The results of this experiment were very striking. After the same premonitory symptoms which were observed in Groups A and C of Experiment II well marked oedema of the legs developed in all the subjects taking the suspected oil. In three cases there was dilatation of the heart. In one patient foetal type of rhythm and in another systolic bruit were heard, there were no symptoms referable to the nervous system. In short, in the judgement of competent physicians the signs and symptoms in these cases were identical with those found in mild cases of epidemic dropsy. The controls remained perfectly healthy.

Discussion

In the absence of exact knowledge of the causal agent epidemic dropsy can only be defined as a clinical entity. Descriptions of different observers vary to a certain extent. It is therefore possible that this condition, like so many other diseases, such as croup and the enteric fevers, may in course of time be split up into two or more distinct diseases on the basis of their aetiology which may possibly be entirely different for these really distinct but allied clinical entities. The clinical feature on which we have mainly relied for distinguishing the condition which we have called epidemic dropsy from what has been described as 'wet beri beri' is the entire absence of signs of involvement of the nervous system. In this respect and in general symptomatology the cases met with in the course of field investigations and those developed under experimental conditions were exactly alike. At any rate the present position may, we think be stated in the following words.

The clinical condition known as epidemic dropsy (or beri beri by lay people), as commonly met with in endemic or epidemic form in Assam and Bengal and in parts of Bihar and Orissa and occasionally outside these boundaries mostly among emigrants from these provinces is caused by some unknown substance or substances which enter the system through the ingestion of food cooked in certain consignments of mustard oil. The oil may be genuine and unadulterated. The nature of the poisonous substance is not known. There is some evidence in favour of the view that the deleterious substance is not a normal constituent of mustard oil and that it is more likely to be a chemical poison rather than something in the nature of a living virus. However inquiries are in progress to clarify this point and to develop if possible

a test by which bad oil may be distinguished from the harmless one

While the problem of the aetiology of epidemic dropsy cannot be said to have been completely solved a definite advance has been made and a stage has been reached when preventive measures, based on scientifically proved facts, can be recommended though their application is limited to a certain extent by the absence of knowledge about the nature and origin of the deleterious substance in the mustard oil. It should now be the duty of the health administrator to trace the oil which has caused the disease to its source as soon as he comes across cases of epidemic dropsy, and to prevent its further distribution. He should also prohibit its use for cooking purposes. The discarded oil may be used for oil baths, as it is probably harmless when applied externally. Besides, there are many other uses to which this oil can be put. The length of the incubation period or the lag phase—five days for premonitory symptoms and nine to twenty three days for development of oedema, as noticed in our human experiments—should be of assistance in tracing the bad oil. By adopting the measures recommended above it should be possible to prevent the spread of the disease among those who have not yet partaken of the oil and to reduce the severity of the disease in those who have taken it in just sufficient quantities to cause premonitory symptoms.

Summary

1 A brief statement is given of the results of epidemiological studies in connexion with outbreaks of epidemic dropsy in seven localities in Bihar, Bengal, Assam and Orissa, representing rural, semi rural, urban, and industrial conditions.

2 An epidemiological experiment designed to test the contagiousness of the disease in a semi isolated community is briefly described.

3 Three principal theories of the aetiology of the disease are discussed, and it is shown that the observed facts fail to support the "diseased rice" theory and the "contagion" theory. A very satisfactory explanation of these facts is provided by the hypothesis that epidemic dropsy, as commonly seen in these provinces, is caused by a deleterious substance contained in certain consignments of mustard oil.

4 Experiments on human subjects, living under strictly controlled conditions, are described. They show that signs and symptoms of epidemic dropsy are produced in healthy young men by giving them food cooked in a brand of mustard oil which is strongly suspected, on epidemiological grounds, of being responsible for an epidemic—the "diseased" rice having been altogether excluded from the experimental food.

5 Practical application of these findings is discussed.

ACKNOWLEDGEMENTS

We gratefully acknowledge the help and co operation which we received from our colleagues in the Calcutta School of Tropical Medicine and the All India Institute of Hygiene and Public Health and from the officers of the Jail Department. In this connexion the names of Brevet Colonel R. N. Chopra C.I.E. K.H.P., I.M.S., Major General D. P. Goil K.H.P. I.M.S., Lieut. Colonel Vere Hodge I.M.S., Dr. R. N. Chowdhury, Lieut. Colonel M. A. Singh, I.M.S., Major S. L. Patney I.M.S. and Lieut. Colonel M. Das I.M.S. deserve special mention. We are thankful to the Indian Research Fund Association for financing the inquiry. We also wish to convey our thanks to the official and non-official agencies which extended their co operation in the course of field investigations.

AN INEXPENSIVE FLOW METER AND HUMIDIFIER FOR ADMINISTERING OXYGEN

BY

I. P. POULTON, D.M., F.R.C.P.

Physician to Guy's Hospital

For the efficient administration of oxygen the rate of flow must be known and this is particularly important now that its relation to the percentage of oxygen in the alveolar air has been established for many different methods of administration. The dial flow meter which is often added to the reducing valve of the oxygen cylinder, because it is really a pressure gauge, may give inaccurate results, and the apparatus recently described by Marriott and Robson is expensive since most of the parts have to be specially made and each apparatus must be calibrated by experiment.

The Apparatus

The present flow meter consists of two tins with lids (A) 7 inches high and $3\frac{1}{4}$ inches in diameter, soldered on to a piece of tin plate (see Figure). These tins are connected

by a German silver (nickel) tube (C-C) $3\frac{1}{4}$ inches long with a diameter between 107 and 108 thousandths of an inch, the tube projects for some distance into each tin. The oxygen passes in and out of the flow meter by the side tubes (B), the nickel tube provides a resistance so that the pressure in the proximal tin is higher than in the distal tin the flow being measured by the difference between these pressures. The pressure gauge consists of

two short pieces of small bore metal tubing (D) soldered into each tin near the top so that they bend downwards into the opening of a boiling-tube (F), 6 inches long 1 inch in diameter, which is held up against and so supported by the nickel tube two glass tubes attached by rubber connexions to the tubes D pass down to the bottom of F, which is filled with water, tinted with red ink to such a height that when in use the surface of the water in the distal tube is level with the zero of graduations marked on one or other of the tins. Then the level in the proximal tube gives the volume of the flow in litres per minute.

Before making up the apparatus the lumen of the nickel tube must be seen to be clear and the openings smooth, when finished the appliance is painted inside and out with several layers of cellulose paint to prevent rust, care being taken that the ends of the nickel tube are not painted over. The apparatus has also been made out of tinned copper. Any slight variation in the length of the nickel tube will not matter, but the diameter should be correct to within a thousandth of an inch. The calibration is as follows:

Pressure difference (mm)	6.5	9	17	27	40	48	57	67	76	85	95	115
Flow l per minute	1.5	2	3	4	5	5.5	6	6.5	7	7.5	8	9

In using the instrument the flow must always be increased up to the value required, too high a reading will be obtained if the flow is diminished from a higher to a lower value. To humidify the oxygen up to 60 or 70 per cent relative humidity an ounce of water is poured into each tin. The oxygen passes over and not through the water.

Advantages of the Apparatus

Flow meters arranged on this principle have been in use for many years, and the only advantages claimed for the present arrangement are that these flow meters can be made up in quantity in the works department of a hospital for a few shillings each, so that where oxygen is often used there should be no difficulty in supplying two or three to each ward, no experimental calibration is required and the flow meter is unbreakable apart from the glass parts, which are renewable from stock, the pressure gauge acts as a safety valve. The flow meter registers from $1\frac{1}{2}$ to 9 litres or more per minute, resistance to outflow—for example from a small nasal catheter—makes no difference to the accuracy, but peripheral resistance should be as low as possible.

Theoretically the apparatus consists essentially of one narrow tube connecting two wider tubes. I should like to thank Mr E M Poulton for pointing out at an early stage of the work that unless the two wide tubes were large in diameter in comparison with the nickel tube the flow would have an inverse relation to the diameter of these larger tubes, such was proved to be the case and consequently two relatively large tins were chosen.

The narrow orifice between convergent and divergent conical tubes was developed by Clemens Herschel in 1881 for commercial gas meters. He called it the venturi opening after E B Venturi the Italian who described it before A.D. 1800. The essential element is the divergent cone which guides the stream of air as it issues from the orifice and modifies by its dimensions the relation between pressure and velocity. The name is hardly appropriate to the present arrangement because the stream issues into a large open space and is not guided in any way. The flow of air or liquid along smooth round tubes has a stream

line flow at low velocities with the pressure difference proportional to the velocity of the flow, at higher velocities the stream becomes turbulent and the pressure difference is proportional to the square of the velocity. The velocity at which the flow becomes turbulent can be determined by the expression $\frac{VDW}{\mu}$ (Reynolds's criterion)

where V is the velocity, W is the density, μ is the coefficient of viscosity, and D is the diameter of the tube along which the gas is flowing.

In the present case calculations for which I am indebted to Messrs George Kent Ltd show that in the ordinary use of the apparatus the velocity of oxygen in the tube is in the "mixed" or "unstable" region between streamline and turbulent flows, and at 8 litres per minute the pressure required to force the oxygen through the tube was due five times as much to turbulence as to viscous resistance between the fluid and the wall of the tube. This indicates that the length of the tube is not of great consequence in determining the velocity, but the diameter and the square-cut, clean circular nature of the entry are all-important, because most of the pressure difference takes place at this point while there is little change of pressure at the point of exit. The essence of the venturi opening is that the loss of pressure energy which occurs in the convergent cone is mostly regained in the divergent cone so that no exceptional head of pressure is required to drive the gas through the opening and the meter is economical in working. This type of economy is of no importance in measuring oxygen, since there is always excess of pressure available. In calibrating this instrument it was found empirically that when $\log(p+1)$ was plotted on semi logarithmic paper against V the result was nearly a straight line (p = pressure, V = velocity).

The easiest way to determine the diameter of the tube is to measure the volume of a $3\frac{1}{2}$ -inch length. For this purpose a short piece of pressure tubing is fitted tightly round the tip of a 1 c.c. graduated pipette so that one end of the tubing is level with the tip. The nickel tube is held just out of the horizontal against the rubber, and ethyl or the cheaper isopropyl alcohol is run into the tube from the pipette. The volume found was 0.52 c.c., which means a diameter of 0.1076 inch.

The flow meter is made by Down Bros. Ltd. St Thomas's St SE1. The tins can be obtained from Wyatt and Co. Tanner Street SE1 and the nickel tube from Johnson Matthey and Co. Hadyn Park Works Askew Road Shepherd's Bush W12.

Part of the incidental expenses were defrayed by a research grant from the Medical Research Council. I should like to thank Mr T W Adams for kindly helping with the calibration.

The third international medical week organized by the *Journal Suisse de Médecine* will be held at Interlaken from August 29 to September 4. Among those who will deliver addresses are Professor Hugh Cairns who will deal with the results of treating intracranial tumours, Dr Clovis Vincent of Paris who will discuss the treatment of subacute and chronic abscesses of the brain, Dr H C Hagedorn of Denmark who will survey the progress made in insulin therapy, Dr R Rossle of Berlin who will consider the hereditary aspects of syphilis and tuberculosis, and Dr H von Meyenburg of Zurich who will lecture on the diseases of cartilages. One day will be spent in an excursion to Berne under the direction of the Faculty of Medicine in that city. The fee for membership is ten Swiss francs and a full programme may be obtained from the secretary, *Journal Suisse de Médecine*, Klosterberg 27, Basle.

TREATMENT OF TRICHOMONAS VAGINITIS BY SILVER PICRATE

BY

W NEVILLE MASCALL, M A Cantab, M R C S
L R C P

Chief Assistant Medical Officer Whitechapel Clinic
Turner Street L C C

It is evident that very little is known about the organism *Trichomonas vaginalis* beyond the fact that it occurs in the secretions of many cases of severe and recurrent vaginitis and that the condition definitely improves when the parasite is eradicated from the vaginal secretion.

The notorious feature about the infestation is the frequency with which the organisms reappear in the vaginal secretion either after the occurrence of the menstrual period or after the suspension of treatment. In the present state of our knowledge it is impossible to say whether this reappearance is due to a reinfection or to a relapse of the primary condition as the source of the parasite and the mode of the infection are unknown.

Diagnosis

The method of demonstrating the *Trichomonas vaginalis* in the vaginal secretion is as follows:

A bead of pus is removed from the posterior fornix by means of a sterile platinum loop and is suspended in normal saline on a microscopical slide. This suspension is covered by a cover slip and immediately examined by the dark ground illumination method and the characteristic movements of the actively motile organism observed.

Many lines of attack have been devised for the treatment of vaginitis due to the trichomonas, and the object of this paper is to bring forward a new therapeutic agent which although used extensively in the United States of America is comparatively unknown in this country. This agent is known as silver picrate, and is put up in two forms both of which are employed in the treatment of the condition: (a) a greenish yellow powder in phials each containing 5 grains; (b) suppositories each containing 2 grains. Shelanski (1936), during his laboratory investigations of the toxicity of silver picrate on the *Trichomonas vaginalis* found that if this compound contained 30 per cent. of silver it was superior to silver nitrate, picric acid, and various other combinations of silver and picric acid.

Line of Treatment

If a positive was recorded the patient was insufflated by means of a Shelanski insufflator (see figure) in the following manner:

The patient is placed on a table in the lithotomy position. A speculum is inserted and the vagina swabbed out with a cotton wool swab. The cervix is closely inspected and any mucus if present in the cervical canal is removed by means of a Playfair probe soaked in saturated sodium bicarbonate.

After removal of the label from the phial it is attached to the insufflator. Each phial contains the correct amount of powder for one treatment, and the screw thread on the phials is so made that each one fits that on the insufflator. The nozzle of the instrument is then gently inserted into the vagina until the rubber shield fills the vaginal introitus. By pumping the rubber bulb the powder is forced out into the vagina until the entire contents of the phial are exhausted.

The instrument may have to be slightly withdrawn at intervals to allow the pressure in the vagina to be eased. By this method the vagina is ballooned, so allowing the powder to penetrate into all the creases and folds. The

patient is then advised to attend daily, when the vagina is again swabbed out and a silver picrate pessary inserted.

The following points should be observed:

- 1 No pain should be caused during the insufflation.
- 2 The pessary treatment is repeated daily for six days and it is then followed by another insufflation.
- 3 After the pessary has been inserted a dry gauze plug thirty-six inches in length may be lightly packed into the vagina to avoid any leakage.
- 4 If the patient is unable to attend daily she is directed and instructed to insert the pessary herself each night on retiring.
- 5 No douching should be allowed during the course of treatment.
- 6 No treatment is given during the menstrual period.
- 7 In pregnant cases it is perhaps best to rely on the pessaries alone, but insufflation is not definitely contra-indicated.
- 8 The duration of the treatment depends on the disappearance of the organism and the signs and symptoms.

Clinical Trial

Patients suffering from vaginal infestation with the *Trichomonas vaginalis* attended daily, and before the treatment was given a suspension was examined and the presence or absence of the parasite was noted. Examinations were also made after the menstrual period as it is at this time that recurrence of the infestation is most likely to happen.

The full treatment consisted of insufflation followed by daily dry swabbing and insertion of a pessary. In the series of twenty-eight cases receiving the full treatment the following results were obtained:

Upon insufflation the *Trichomonas vaginalis* disappeared on the next day from the secretion in twenty-six cases (92.8 per cent.).

In the two cases in which the trichomonas was present on the second examination it was observed that the numbers had decreased and that the organisms were sluggish in movement. The parasites were absent on the third examination.

Of the twenty-eight cases fifteen (53.5 per cent.) remained persistently negative, but in thirteen (46.4 per cent.) a relapse or reinfection occurred.

Of the relapses or reinfections five (38.4 per cent.) occurred following a menstrual period and eight (61.5 per cent.) occurred at times other than after the menstrual period.

Total cases	28
Cases negative following insufflation	26 (92.8%)
No relapses	15 (53.5%)
Total relapses	13 (46.4%)

Of the relapses

(a) Occurring after the menstrual period	5 (38.4%)
(b) Occurring at other times	8 (61.5%)

One pregnant case not in the above series was treated by pessaries only, and the trichomonas disappeared after the first treatment it recurred however, on the next day, but afterwards the case remained persistently negative. In all cases the local condition showed marked clinical improvement, the discharge becoming markedly less in amount, local inflammatory signs settling down, and such symptoms as irritation and soreness abating, in spite of the fact that in eleven of the cases there was coexisting gonococcal infection.

My thanks are due to Colonel Burke for permitting me to publish these observations.

Clinical Memoranda

The Emotional Factor in the Causation of Squint

In a recent article on the care of children's eyes, in a popular journal devoted to the service of childhood and youth, an ophthalmic surgeon wrote: "Several observers have lately remarked on the frequent association of squint with a nervous disposition. There are authentic instances of a squint having dated from some fright, or from some occasion for jealousy such as the birth of a baby sister or brother. Anxiety can be a factor in its development." I wrote about these matters many years ago (*An Inquiry into the Origin of Squint, Left handedness and Stammer, Lancet* August 2, 1924) and now once more suggest that an emotional cause of squint is far commoner than is suspected. Unfortunately the connexion is not recognized, because surgeons and parents have still to learn the lesson psychologists have been teaching for decades—that what a very young child sees and hears may sometimes induce not only emotional distress but even actual illness. The subtlety of the circumstances may be gauged from the following case.

A CASE IN POINT

A boy aged 2 years and 4 months began to squint in November 1936 six weeks before he was brought to me. The deformity was not constant, in contrast to nearly every squint that I have seen it was present not when the child was excited—the eyes were then usually straight—but when he became dreamy. A logical approach to the problem surely would be to find out what he was dreaming about for none of the usual explanations of convergent squint is adequate to account for convergent activity during apparent dreamy relaxation. As every one knows the eyes become straight and have a far-away look during a brown study.

Unfortunately it is not possible to get evidence by questioning so young a child and support for surmise must be sought indirectly. There is no more helpful beginning to an investigation of a child's troubles than to know how the mother was faring at the time the troubles developed.

To the question "What was wrong with you six weeks ago," the mother Mrs. X., replied, "I had influenza—the squint developed when I began to take the child out again."

"Has he had any other symptoms since the squint began?"

"No, but he has been cutting his last two teeth during that time."

"No bed wetting?"

"Well he has always wetted his bed with the cutting of every tooth and it has been especially troublesome in the last six weeks."

Truly a strange association of functions! How far it was dependent upon oral stresses at a still earlier phase is worthy of more detailed inquiry, since it is astonishing how often mothers comment upon the greater frequency of squint—another neurosis—during meal times. At this point I merely used it for a guess that the child had taken weaning unusually hardly. The mother agreed there had been much difficulty when it took place at the end of ten months.

Incidentally it is scarcely necessary to ask if the child sleeps in the parents' room, such a child as is before me *always* seems to do so! I then tell the mother that experience leads me to suspect that six weeks ago she was exceptionally interested in the birth of a baby, not necessarily her own, perhaps the interest was in childbirth generally rather than in an actual confinement. This she denies and I seem to have drawn a blank. But I still feel that the parent-child relationship may be responsible for the breakdown of binocular vision, and ask: "Hadn't you a bad monthly period six weeks ago?" I have found that even little children have an uncanny awareness of that function. The mother, after some hesitation, admits the truth: "Yes, as a matter of fact I had a miscarriage two months ago, and the bleeding continued for three weeks."

Thus the squint must have begun at a time when the child was seeing and hearing matters that four or five years later he would be carefully protected from seeing and hearing, imagination can now be invoked to visualize the situation in the bedroom shared by the child. Let it be remembered that the squint was not an instant and permanent reaction, it was delayed and inconstant. Indeed, at first it showed only when the child was *dreamy*. Have we here some indication of what he might be dreaming about? If we may take the daydreams of adults for comparison, it seems probable that the child's thoughts had no conscious definite shape, but that they were connected with a threat to the security of the love relationship with the mother seems likely. The sight of blood to a child—and the mother could not deny that her little boy had had many opportunities of seeing blood at that time—is full of significance of danger even at the age of 2. It is true that this view is only a surmise, even the mother could not divine what was in the mind of her little boy. But in spite of her early resistance to my suggestions she readily accepted them later when the situation was reconstructed for her—a sensitive observant child sleeping in the parents' room with the beloved mother ill and depressed, suffering from some mysterious ailment associated with bleeding from which she was making a slow recovery. She was further impressed when I asked for the history of left handedness and stammering in the family. She declared herself to be wholly right handed, though she had a left handed brother but she had stammered at the age of 3 when a baby brother was born. I have found that adults with such a history usually retain some significant if apparently trivial left handed sign of former contrariness, and after further thought she called to mind that she always mounted a bicycle from the "wrong" side.

But let us apply the same formula of mother-child relationship to Mrs. X. herself. In the eventful November her own father and mother had been discussing separation to Mrs. X.'s great distress, for the father had threatened to commit suicide if his wife left him. May we not assume that these tragic circumstances helped towards her miscarriage and the squint in the frightened baby observer?

Reviews

A SUMMARY OF MODERN MEDICINE

A Textbook of Medicine By Charles Phillips Emerson
M.D. (Pp 1296 36s net) London and Philadelphia
J B Lippincott Co 1937

A new textbook of medicine by Professor Emerson follows the teaching of the Johns Hopkins school and presents a good summary of modern medicine. The grouping of subjects is on the usual lines beginning with diseases of known aetiology infectious protozoal, toxic, and allergic and diseases of metabolism and deficiency, and there follows a discussion of system diseases according to the part of the body affected. The author has attempted and appears to have succeeded in portraying the clinical pictures of diseases as they are likely to be met by physicians and medical students. Each group of diseases is approached from the historical side, and the sections are enlivened with short accounts of the development of our knowledge with the names and contributions of the older workers. The systematic descriptions of aetiology, symptoms, complications, diagnosis, prognosis, and treatment are shortly and clearly written, give a good idea of up-to-date practice, and may be recommended as sound and sufficient.

Professor Emerson, whose book on the nervous patient is well known, has introduced a short chapter on psychoneurotic reactions in disease which directs attention to the need for study of the psychological background in the case of each individual patient. This is necessary for a proper understanding of the case, since treatment on stereotyped conventional lines, though quite correct, may fail to bring the patient back to a complete restoration of health or to prevent him relapsing when he meets the stresses of life again. In the section on nervous diseases the effect of environmental strains of modern life during childhood and adolescence and their repercussions in the time of the climacteric of man or woman is dwelt upon. Each disease syndrome is regarded as an expression of a protective biological reaction to a particular invading germ, or an attempted adjustment of function in spite of lesions in one organ or in others functionally related to them, treatment should aim not to suppress symptoms but to render them unnecessary, and when the attitude towards disease inculcated in this book is adopted the practitioner will become not only an erudite but a skilled and understanding physician.

The book is convenient to handle, has a good index, and few misprints. There are no illustrations. The author states that he has had the opportunity of preparing this work by his appointment as research professor of Indiana University and he has made good use of it.

MOVEMENTS OF INTERNAL ORGANS

Röntgenkymographische Bewegungslehre Inneren Organe
By Dr Pleikart Stumpf Dr H H Weber and Dr H Weltz. (Pp 516 447 figures M 42 geb M 44)
Leipzig G Thieme 1936

This Röntgen kymographic study of the movements of the internal organs by Dr Pleikart Stumpf and others, is a very full description of a method of investigation of the movement of the heart, and the movements of the stomach oesophagus lungs and ureters, rendered visible by radio-opaque contents. Briefly the principle depends on two methods. In one a moving plate is used and in the other the plate is fixed but a moving grid is passed

between it and the organ to be studied. The latter is more useful. The result is that the outline of the moving shadow of the organ on the plate takes on a wavy or zig zag appearance. The indentations are modified by the degree and nature of the movement and the plane in which it takes place when considered in relation to the plane of the plate. In many of the illustrations the movements can be reproduced again by passing over the photograph the celluloid grid provided. Probably the heart lends itself best to study by this means and then the stomach.

The question of the change in size of the heart on inspiration appears to be settled. The conclusion is that in quiet breathing the shadow decreases in size, but deep forced inspiration may cause an increase in size. It is claimed that the origin of extrasystoles can be distinguished, but there is little electrocardiographic confirmation, and the curves of extrasystoles are interpreted in a way many authorities now hold to be incorrect. The amplitude of the contractions of the heart seems to have some significance and the tracings give a good deal of information on this point. There is some evidence to show that alternation of the heart beat is associated with only partial contraction of the ventricle. The author gives a full study of the effect of valvular lesions on movements of the heart.

Examination of the stomach shows the changes in peristalsis due to the presence of ulcers and growths or to pyloric obstruction. Gastritis affects the folds of the mucosa and reduces their movements. Röntgen kymography of the urinary tract has been little exploited so far, technical difficulties are considerable, but the author hopes for good results.

The book opens up an interesting field. Much experience and study are needed to understand the many implications of this method. Interpretation of the finer changes in the shadow movements especially those of the heart, is clearly very difficult. That these differences exist is obvious on examining the photographs, but there must still be a good deal of doubt as to what they mean. The illustrations are excellent the print good, and the references full and clearly set out. It is a pity that an important work of this nature, covering such a wide field, is not provided with an index.

ORTHOPAEDIC CONDITIONS

Elements of Orthopaedic Surgery By N Ross Smith,
M.B. Ch.M. F.R.C.S. (Pp 246 99 figures 10s 6d net)
Bristol John Wright and Sons London Simpkin
Marshall 1937

A short book on a big subject is written either for those who wish to widen their field of interests without intending to make practical use of their newly acquired knowledge or, on the other hand, for those who require a limited acquaintance with the particular subject that will be of value in everyday work. Mr Ross Smith's book may satisfy the first but it is not likely to be of much value to the second. It is intended to be a "practical account of the elements of orthopaedic surgery for practitioners and students who do not require the full knowledge given by larger textbooks and for nurses and masseuses engaged in orthopaedic work. This should mean that diagnosis is given a pre eminent position. Pathology and the details of treatment, however interesting are of little practical value until the reader knows how to recognize the clinical conditions concerned. Orthopaedic surgery demands life long devotion from those who try to master its intricacies, and the treatment of cases of deformity should be concentrated in the hands of those specially qualified for this work. But successful treatment so often depends upon

early diagnosis that the part played by the general practitioner or the orthopaedic nurse is of the first importance. They see the patient when the lesion is only just declaring itself, and the early or late arrival of the patient at the orthopaedic clinic depends, very often, on their powers of observation and the correct appraisal of what they see. This book should tell the doctor or nurse what to look for. Having discharged this important duty it might, in addition, give the broad outlines of treatment. Unfortunately it presents nothing more than a rambling account of the conditions commonly called 'orthopaedic,' with but few references to many useful advances that have been made during recent years.

Let us take a few examples. All orthopaedic surgeons are anxious to see cases of rigid kyphosis of adolescence in the early stages of the disease, and it is probably a fairly common condition. The author dismisses it in one sentence with not even a hint that early diagnosis and treatment may save the patient from developing a severe fixed deformity. Ewing's tumour, by contrast, has a page all to itself. In the chapter on tuberculosis of bones and joints no guidance is given for the investigation of the intermittent limp, the odd joint pain, the slight puffiness that may herald the onset of disease in the hip or knee. How is tuberculous disease to be distinguished from the common non-specific arthritis of childhood? We are not told. 'An x-ray examination gives valuable information and is essential in all cases. Essential no doubt, but the information given is often distressingly vague. Nothing is said even about the radiographic signs that are of real value in the early case, such as the enlargement of the patellar nucleus in tuberculous disease of the knee or narrowing of the disk space in disease of the spine. Spinal fusion, however, is allowed two pages and a plate. Such examples could be multiplied.

Provided that the reader realizes early that this is not a practical book as usually understood he may not be disappointed. It is interesting, fairly accurate, pleasantly written, faultlessly produced, and not expensive.

SPIRITUAL HEALING

The Background of Spiritual Healing. Psychological and Religious. By A. Graham Ikin M.A. M.Sc. (Pp. 224. 6s. net.) London: G. Allen and Unwin, 1937.

There are few subjects on which it is more difficult to get one's mind clear than that of 'faith healing' or 'spiritual healing' to use expressions commonly used to indicate that which others prefer to speak of as the Church's ministry of healing. Recently there have been published several books which go some way towards such clarification of mind though none of them appears completely to accomplish it. That depends doubtless, not only on the nature of the subject but also on the facts that both author and reader have usually already adopted a fairly definite attitude either religious or psychological, ecclesiastical or scientific, that the axioms or postulates with which they start differ and sometimes that the language in which they express themselves is not identical. Nevertheless such books are often very helpful, and among the most helpful of these must be placed Miss A. G. Ikin's *The Background of Spiritual Healing*. Miss Ikin's position, qualifications, and experience have now become well known and she writes with authority as a research scholar and lecturer in psychology, and as the psychologist working under the Archbishop of York's committee of doctors and clergy. Her book is written from what may be regarded as a High Anglican point of view and it rather shirks than elucidates such

questions as the place and efficacy of prayer of unction and of the laying on of hands in relation to its main subject, but on that main subject it is an able, thoughtful, and helpful pronouncement.

The book is not markedly biased by its theological point of view or by its preference for some particular psychological school of thought, and one of its best characteristics is the clearness with which the author makes those distinctions, sometimes rather minute, which are so necessary as a foundation for any profitable consideration of this subject. Though the end of the priest and the psychotherapist may be the same—the effecting of a truly harmonized personality—their immediate lines of approach are not identical. The one desires directly the conscious reconciliation of a human personality with God whatever the conception of God may be, the other the cure of a disordered personality. Each, to be really effective, must use not only his own personality but also skilled methods for which training is essential. Cures effected by the reaction of a distinctive personality on the mere emotions of patients without intelligent method or understanding are rarely more than very temporary though they are often dramatic and startling at mass services. Again there is a distinction between spiritual healing and mental healing though these are often confused in popular speech: both religious healing by the priest and psychological healing by the physician may operate on the mental level or on the spiritual level, often on both.

On the basis of ideas in which such distinctions as these are constantly borne in mind, and with a thorough knowledge of psychological theory and a sufficient acquaintance with psychotherapeutic methods and practice, Miss Ikin makes an orderly survey of her 'background'. She proceeds from an evolutionary and historical sketch of the emergence of the spiritual factor in the treatment of disease by way of a consideration of instincts and ideals and a remarkably clear exposition of the organization of instincts and of sentiments, dispositions and complexes to chapters on 'Moral Disease and Sin', on 'Suggestion and Faith', and on 'Psychoanalysis and Confession', and to a final plea for a 'harmony between psychotherapy and the Church's Ministry of Healing' wherein each has its part to play both by way of mutual understanding and of co-operation.

MERCK'S "JAHRESBERICHT"

We welcome the appearance of the jubilee number of Messrs E. Merck's *Jahresbericht*. During the fifty years since its first publication this annual report has increased steadily in importance and usefulness. Indeed during that period the number of new drugs and the relevant literature have increased at such a remarkable speed that to-day it is difficult to keep pace with recent progress without the aid of annual reviews of literature such as are provided by Messrs Merck. Tributes to the value of these reports are paid in a series of jubilee congratulations sent from laboratories all over the world which appear on the opening pages. The greater part of the volume is composed of a general review of literature relating to the therapeutic use of drugs which appeared in 1936. The most impressive point about this review is the mass of the literature dealt with which amounts to nearly 2,000 references. The rate at which any important new discovery accumulates a literature of its own may be gathered from the fact that the *Jahresbericht* gives fifty references to work relating to prontosil and there are over 100 references to recent work on sex hormones. These figures indicate the importance of the report as a guide to a literature that

very mass of which makes it inaccessible to any but a specialist dealing with some selected and narrow field. In addition to this general survey the volume contains also a series of papers, many of which come from the Merck laboratories. Among these may be mentioned an interesting series on recent advances in vitamin chemistry.

Doctors and pharmacists may obtain copies of the jubilee number, printed in German or in French from Messrs E. Merck (Darmstadt), Publicity Department, 60, Welbeck Street, London, W.1, free of charge.

Notes on Books

The sumptuous volume entitled *Christian R. Holmes, Man and Physician* by Dr. MARTIN FISCHER, contains a glowing account of the life and work of the eminent physician of Cincinnati who died in 1920. Born at Vejle in Denmark in 1857, the son of a miller, Holmes first started life as a civil engineer but in 1876 migrated with his family to Cincinnati, where he studied medicine. In 1885 he became an intern to the Cincinnati Hospital, to which he became successively attached in the capacity of curator, physician, otologist and ophthalmologist. Many years of his life were spent in visiting hospitals in the United States and Europe in order to gain information likely to be useful for improvement of his hospital. In 1904 he was appointed professor of otology and dean of the University of Cincinnati. During the great war he was put in charge of the ear, nose, and throat department at Camp Sherman, Ohio. Holmes made numerous contributions to the literature of hospital construction and medical education, as well as to that of oto-rhino-laryngology. He was president of the American Academy of Ophthalmology and Otology in 1901-2, and of the Cincinnati Academy of Medicine, and vice-president of the American Medical Association in 1902-3. The text is interspersed with portraits of Holmes at various stages of his career and members of his family, as well as of the Cincinnati Hospital. The work is published by Charles C. Thomas, Springfield, Illinois, price 4 dollars, and in this country by Ballière, Tindall and Cox.

A Moth Hunter's Gossip is aptly, though modestly, described by the author, Mr. P. B. M. ALLAN as "merely little tattle about certain moths which happen to interest me." These are more especially the sphinges or hawk-moths, and the book contains much information on their habits, also reminiscences on collecting, although the author confesses to his credit that he is more interested in live than in dead insects. This is a book for the leisure hours of entomologists, and some knowledge of the subject, extending at least to a familiarity with the Latin names of the various species, is necessary for its proper appreciation. It is published by P. Allan and Co. at 7s. 6d.

In the work entitled *Syphilis sive morbus Humanus* (Lancaster, Pennsylvania: Science Press Printing Co.) Dr. CHARLES S. BUTLER, rear-admiral in the United States Navy, states that his object is first to give popular knowledge concerning venereal diseases, secondly to expose the fallacy of the American origin of syphilis, and thirdly to show the unity of so-called "yaws" and syphilis. As regards the first claim, Dr. Butler urges that popular education in sexual diseases should be carried out by newspapers, moving pictures, and other means of popular education, and that the victim of venereal disease should be treated just like any other sick person. Unlike Astruc in the eighteenth century and Wilhelm Ebstein, Iwan Bloch, Preuss and Jeanselme in modern times, whose work he ignores, Dr. Butler maintains that certain diseases mentioned in the Bible, especially those of David and Job, were syphilis and makes similar statements with regard to the lesions on the genitals described by Celsus, and

in the throat by Aretaeus, which were more probably soft chancre and diphtheria respectively. Dr. Butler's observations on this subject may impress the laity but will not be taken seriously by the medical historian.

The useful little work entitled *Parents' Questions*, which consists as its subtitle states, of detailed answers to the most significant and frequently recurring questions put by parents, has been drawn up by six staff members of the Child Study Association of America. The questions have been arranged in the following categories: habits and habit training; discipline and authority; healthy attitudes towards health, heredity and training; the child's emotions; sex in childhood; character and spiritual growth; school and home; the child and the outside world; and parents as people. The book is published in this country by Gollancz at 8s. 6d.

Preparations and Appliances

NEW PATTERN NEEDLE HOLDER

Mr. G. L. PRESTON, F.R.C.S. Ed. (Plymouth) writes:

I primarily devised this needle holder for use in cleft palate operations in children, but it is equally useful in all operations and in any situation where space is limited and accurate suturing essential. The majority of needle holders were too

massive and cumbersome for the small needles employed. Apart from this, when working in such a confined space one's hand invariably tended to obscure the view of the operation field. Owing to the marked 'cast off' in the handles, the needle is always in view, and the slight curve in the jaws and the fineness of their points enable even the smallest sizes (that is, Lanes) to be held securely in various positions so that the sutures can be inserted from any angle, which is an impossibility with the ordinary types of needle holders. The needle holder has been made for me by Messrs. Down Brothers, London, S.E.

MODIFICATION OF SMITH PETERSEN NAIL

Mr. C. E. KINDERSLEY, F.R.C.S. (Bath), writes:

Messrs. Down Brothers have made for me a modification of the Smith-Petersen nail, which should prevent the danger of the nail carrying the direction wire or pin through into the pelvis. The nail is made after the Viennese pattern, 15 mm

in diameter and the terminal portion of the cannula (2.5 mm) is flared out in order to allow it to slide easily along the guide. This applies to any guide pin which has markings upon it or shoulder cuttings in it. This modification was suggested to me by a case in which the nail caught on a Kirschner wire and carried this an inch or more into the pelvis and fractured the nail itself, leaving the terminal quarter inch of the nail in the head of the femur.

AN EXPERIMENT IN SOCIAL HYGIENE THE CAMPAIGN AGAINST PROSTITUTION AND VENEREAL DISEASE IN THE U.S.S.R

BY

E. H. CLUVER, M.A., M.D., D.P.H.

Union Health Department, Pretoria

Everywhere in Russia one met with problems that were being "liquidated." Certainly that country is attaining the objects it sets itself in its "plans" with remarkable rapidity, which is the less surprising when one becomes aware of the tremendous enthusiasm with which the items of the plans are tackled by everyone concerned.

Prostitution a "Liquidated" Problem

In Moscow I was informed that the problem of prostitution had been almost completely liquidated. The startling optimism of such an assertion made one gasp. And yet on inquiring further into the matter one had to admit that the claim was to a very considerable extent justified by the facts. In Tsarist times Russian cities were notorious for the amount of prostitution rife in them. And of these cities Moscow had much the highest percentage. Yet when I visited Moscow last November only one prophylactorium for the treatment and rehabilitation of prostitutes still remained of the five large institutions established in 1926. In this one prophylactorium the number of inmates had fallen to 100, and in the whole of Moscow, which since the Revolution has, because of industrialization, nearly doubled its population, the authorities knew of only 240 prostitutes, this in spite of the fact that they search for them now much more diligently than in the past because of their active campaign against venereal disease, and that all sorts of inducements are offered to prostitutes to present themselves.

In 1913 there were in Moscow 2,000 registered prostitutes. While reliable statistics as between registered and undetected prostitution are obviously not obtainable, it has been assumed with a fair degree of probability that in countries where regulation of prostitution is practised there are at least ten unregistered for every one registered prostitute. It may be assumed, then, that in Moscow in the years immediately preceding the Revolution there were at least 20,000 prostitutes. Yet now, with every encouragement held out to come for treatment and a very elaborate system of detection, there is work in Moscow for only one prophylactorium, the number of inmates of which is rapidly dwindling. I was informed that it was confidently anticipated that within a year it would have to be closed down, as all prostitutes will have been absorbed into industry.

In Russia as a whole conditions have been similar. The campaign against prostitution was begun in 1917 as one of the first of the "capitalist evils" to be tackled. In 1926 there were in all thirty-three prophylactoria. These have now been reduced to sixteen and it is expected that by the end of the present five-year plan the whole problem will have been liquidated and that there will be no further use for prophylactoria.

The Economic Factor

When I inquired from physicians in the prophylactoria and others as to the reasons for this virtual abolition of prostitution from Russian cities I was invariably informed that the main, if not the only reason was the fact that ample employment was now available for women. Women are now not only on an absolute equality with men as regards equal pay for equal work, but they are completely compensated for their natural disabilities. Thus a woman manual worker gets fifty-six days leave on full pay before confinement and another fifty-six days after confinement. For women employed in non-manual work the periods are forty-two days in each case. The

granting of this leave is rigidly enforced. At one factory the manager somewhat resentfully pointed out to me a pregnant worker who had been taken on only a week previously. In another week she would be within two months of her confinement, and although she would have been at his factory for only a fortnight he would have to continue keeping her on his pay roll for the next sixteen weeks. Having a baby is looked upon in the U.S.S.R. as quite as onerous as factory work and therefore deserving of the same pay. After the period of leave is over the mother is still assisted. Every factory I visited had attached to it a crèche, where not only are infants under skilled care, but the employed mothers can come and nurse them twice during the working shift. The disability due to maternity is thus almost completely removed. Charts are actually provided for the woman worker to read off directly when her pre-confinement spell of leave will fall due.

I have gone into this matter somewhat fully to illustrate the great importance that is attached to the necessity for absolute equality between men and women in the field of labour. Women have become completely emancipated in Russia. One saw them driving trams, train-conducting, managing factories, directing polyclinics. In the medical world men are conspicuous by their absence. At one large polyclinic in Moscow, after I had seen some twenty women doctors at work in its various sections, I commented to the lady director who was showing me round on the absence of men.

"Ah," said she, when my remark had been translated by the female intourist guide, "we are just coming to a section of which a male doctor is in charge."

Even then we were doomed to disappointment for when we reached the point where he should have been he was unaccountably not at his post!

Not only has the female equal opportunity in the labour world with the male, but her services are very greatly in demand owing to the shortage of industrial labour. There is no unemployment in the U.S.S.R. On the contrary, the factory managers are continually complaining of the shortage of labour because of the difficulties resulting in keeping up with the five-year plan of factory production.

This, then—the fact that women have not the slightest difficulty in obtaining fully paid work in legitimate industries and professions—is given as the chief reason for the liquidation of the problem of prostitution.

Contributory Factors

Other factors which are considered to be of minor or contributory importance are propaganda, the facilitation of divorce, and the work of the prophylactoria. Propaganda on the part of the State has become very highly developed in Russia. It results in an almost fanatical fervour for attaining the objects set out by the propagandists. In a land where the vision is nowhere, either on hoardings or in newspapers obscured by the commercial advertisements of capitalist countries, propaganda of this kind becomes particularly effective. (One of the first things that strikes the visitor to the U.S.S.R. is the absence of all advertisements and it is an absence for which he cannot but be grateful.) All forms of propaganda are mobilized in the war against disease: addresses, pamphlets, posters, diagrams in clinics. Those regarding prostitution and venereal disease are frank to a degree and to the Western eye sometimes revolting.

The changed laws of marriage have undoubtedly contributed to the abolition of prostitution. Divorce has been greatly facilitated so that incompatible couples are no longer compelled to live together with the almost inevitable development of immorality. Further legal or clerical sanction for liaisons is no longer insisted on and there is no such thing as an illegitimate child. Nevertheless it is wrong to assert that this relaxing of the bonds of marriage has resulted in promiscuity. This may have

been the case to some extent just after the Revolution, with the sudden relaxing of restraints, but it certainly is no longer true. Divorce, though legally easy of attainment, is yet expensive. A first divorce cost 50 roubles, a second 150, for third or subsequent separations the charge is 300 roubles—that is, a month's wage or salary of an average manual worker or a junior professional worker. If there are children there are more serious financial sanctions. If the children are kept by the mother the father is required to pay a quarter of his wages for one child, a third for two, and a half for three or more. The same applies to the mother should the father have the custody of the children.

Prophylactoria

The prophylactoria merit a brief description if only because of the probability that they will shortly cease to exist. They are institutions for the reform of prostitutes and for the treatment of venereal disease, from which all the inmates suffer on admission. I visited two prophylactoria, the one in Moscow and another in Kiev. But it would appear that the procedures are practically identical in all. The women enter the institution voluntarily, presumably after they have been reasoned with by social workers specially trained for the purpose. I was positively assured, however, that there is no police interference whatever with the prostitutes. The girls normally remain in the institution for two years. They receive intensive treatment for their syphilis and/or gonorrhoea during the first week or two after admission. Treatment continues throughout the period of their stay, but after the active manifestations of disease have been cleared up training to fit them for occupation in industry begins. If they are illiterate they receive ordinary primary education. But an essential feature is the technical training designed to fit the girl for a job when she leaves. At Moscow most of the inmates were being trained in needlework in a special needlework shop attached to the institution. For their work they are paid the same wages as those received by workers in ordinary factories. There is no philanthropy. The girl becomes a worker from the first day after she has completed her course of active treatment receiving on an average 70 roubles per month. Of this 35 roubles are deducted for food and use of dormitory. True she receives treatment and education free, but this applies throughout the U.S.S.R., all schools, clinics, and hospitals supplying their services free. A proportion of the patients are mentally deficient. For them other training is provided. Not infrequently they take readily to simple singing and painting.

The ages of the inmates varied from 18 to 24 years. At the Moscow institution ten full-time physicians were employed. To account for this surprisingly large number for only 100 patients it was explained that psychiatric treatment is looked upon as of very great importance. Such treatment is necessarily laborious and slow. The staff, then, consists of psychologists, neuro-pathologists as well as ordinary veneerologists. The institute was well equipped with all the usual requirements of a hospital for venereal diseases, including a bacteriological laboratory, a urological department, and a theatre for physiotherapy.

During the twelve years of its existence the Moscow prophylactorium has dealt with approximately 2,500 cases. Only about 1 per cent of those discharged revert to prostitution. Most of them have married and had children. Others have entered schools and universities for which they are given special facilities. The institute keeps in touch with the girls after discharge, although this is done unobtrusively. The subjects being in most cases unaware of this supervision. Supervision ceases when the authorities are satisfied that all danger of reversion to prostitution is past. Thus of the 2,500 girls that have passed through the Moscow institution 500 only are still under supervision.

It will be realized that each prophylactorium has a special outdoor staff whose duties are not only to supervise the women discharged from the institute but also to be on the look-out for hitherto unrecognized prostitutes. They visit bazaars, railway stations and other places where soliciting is likely to occur. They maintain that they have no difficulty in recognizing the prostitute. It is by means of this staff that it has been possible to estimate the number of prostitutes in Moscow at present as only 240 in contrast to the 20,000 or more of two decades ago. It is the members of this staff too, who engage in conversation girls seen soliciting, telling them of the opportunities offered by the prophylactorium for treatment of the venereal disease from which they are probably suffering and of the facilities for being trained in a more honourable occupation.

A matter which I did not hear discussed in Russia was the male factor in prostitution. Obviously female prostitution cannot flourish unless there is a large population of males seeking its services—the ordinary callous assumption that the supply is largely created by the demand. This demand I should imagine has largely disappeared because of the simpler marriage laws and (what seems to me even more important) the enthusiasm of every citizen for the new conditions. Every Russian one met was clearly convinced that his was the best form of government, and it was up to him to do his utmost to demonstrate to the rest of the world what a fine fellow a member of the Russian proletariat was. With this splendid ardour evil living finds no place. My very first interpreter (as everywhere else a female) told me with pride: 'There is order everywhere.'

Venereal Disease

With prostitution so nearly abolished venereal disease must automatically have greatly diminished. Apart from venality (commercialism) prostitution implies promiscuity and the inevitable harvest of promiscuity is venereal disease. Other factors promoting a decrease in incidence are the greatly increased facilities for diagnosis and treatment, the clean certificate of health required before marriage, and the inevitable propaganda.

The factors which have been mentioned as conducive to the abolition of prostitution all act indirectly, too, in lessening infection. They are all factors aimed against promiscuity, and therefore also against venereal disease. A more direct campaign against these diseases is also being waged. All five of the cities visited by me in European Russia had ample laboratory facilities for diagnosis as well as hospital and dispensary accommodation for patients suffering from venereal disease. Diagnosis and treatment is, of course, entirely gratuitous. Further, they appear to have been amazingly successful in removing all stigma attaching to infection. These diseases are looked upon as a misfortune comparable to any other infection which may have been contracted. On the other hand, the patient is given full information about the infectivity of his condition, and if he wittingly transmits infection to another he is very severely dealt with. Such a crime is punishable with six months imprisonment. Patients who are not amenable to persuasion and who will not take the requisite precautions are dealt with in various ways the most effective of which is by means of the wall newspaper, which one sees in every factory. A patient who refuses to come for treatment has this fact announced on the wall newspaper of his factory, with the added information that he is a danger to his fellows.

Before the Revolution the level of living was so low that there was a tremendous amount of innocent syphilis—that is, infection conveyed extragenitally. This resulted from gross overcrowding in hovels or tenement rooms, all members of the family using the same eating utensils, and the many other well known ways in which infection of this nature must necessarily spread when persons are living in the very lowest levels of degradation. The

obvious general improvement in the level of living of these people, together with preventive propaganda and education, has largely removed this form of venereal disease

Accurate figures regarding venereal disease are not yet available even in Russia, where the reticence which is so great an obstacle has largely been removed. Nevertheless there can be no doubt that the incidence has, during recent years, been very greatly reduced, and from the medical point of view this is one of the obvious and very notable successes resulting from a mighty experiment in social hygiene

Nova et Vetera

HISTORY OF GYNAECOLOGY AND OBSTETRICS

Dr Edwin Jameson's small pocket book on this subject¹ is one of the series of primers on the history of medicine issued under the general title *Clio Medica* and edited by E. B. Krumbhaar of Philadelphia. The author, in a modest introduction, recognizes the difficulty of dealing adequately in a small volume with the history of gynaecology and obstetrics, while "hoping that he has brought to light a few new facts or new points of interest." In this he has certainly succeeded. Dr Jameson does not cite his sources in the text, but appends a bibliography and a list of classic books. The first four chapters deal with the subject under Early Period, Greek and Roman Period, the Renaissance, and Modern Period. The author, in writing of Caesarean section spells it Caesarian, and says the word may be derived from the Latin word *cedere* though it should be *caedere*—*a matris utero caesus* (Pliny). The date of publication of *The Byrth of Man-kynde* is given as 1545, it should be 1540. The important Italian Renaissance work, *La Comare* published by Scipione Mercurio in 1596, should have been mentioned. Mercurio was known by several names—for example, Scipion Mercuri or Mercurii, but not by the name of Mereurali, under which he appears in the index. Jerome (Hieronymus) was his monastic name. The author mentions the *Gynaeciorum* of 1566 and 1586, but not the more important Spachius edition of 1597. An interesting account is given of the foundation of the first lying-in hospital in America by Dr W. Shippen in 1765 just twenty years after the foundation of the Rotunda in Dublin. Dr T. C. James (professor in 1813) is mentioned as the first in America to induce premature labour in a patient with contracted pelvis, but there is no account of the history of the operation in England from 1756 to the present time. The author does well to call attention to the opposition shown to the Maternity Hospital in Philadelphia and to the futile endeavours to restrict the surgical activities of obstetricians.

No less than one third of the book is taken up with the history of the forceps and puerperal fever, leaving only thirty-three pages for the development of gynaecological surgery. We think these chapters might have been curtailed with advantage: the classic work of Kedarnath Das on the forceps is not mentioned. The pair of Chamberlen forceps illustrated is not the most interesting of the Chamberlen instruments which are preserved in the library of the Royal Society of Medicine (not as stated, in the museum of the College of Physicians). A reference is given to O. W. Holmes's valuable contribution to the study of puerperal fever and his eight conclusions are published.

As the author states the chapter on the development of gynaecological surgery is extremely sketchy. This is regrettable, in view of the great part Americans have taken in its development and of the fact that its

"father," Marion Sims, founded the first hospital for the diseases of women, Women's Hospital, New York, in 1855. We think that the author minimizes the work of the English ovariologists Charles Clay and Spencer Wells, to whose publications the world-wide adoption of ovariectomy was chiefly due. Up to the year 1860 when the author says the operation had taken root in America, Clay had performed more successful complete operations (65) than the whole of the American gynaecologists (64) and with a mortality rate of 30 per cent. up to that time the chief American ovariologist (Allee) had only performed ten successful operations, with a mortality rate of 45 per cent. It was to the British and not the American operators that the French and Germans flocked to study ovariectomy, as may be read in Spencer's *History of Ovariectomy* (Proc. Roy. Soc. Med., 1924) where also is recorded Emiliani's (not Gaetano's) operation in Italy in 1815, to which the author had not been able to find a reference. We cannot find any account of chorion epithelioma or of the treatment of cancer of the cervix by the electric cautery (Byrne) or radium. In the epilogue the author adds that a monument has been recently erected to the first ovariectomy patient, Mrs. Crawford, in Danville, Kentucky, where a monument to the first ovariectomist, Ephraim McDowell, was erected in 1879.

A few typographical or nominal errors have been noticed: Paen for Péan, Françoise Rousset for François Rousset, Hendrick for Hendrik, DuBois for Dubois, Emiliani Gaetano for Gaetano Emiliani. Generally we have been struck with the accuracy of this little book which will be welcomed by both specialists and general practitioners, for it contains a good deal of information only to be found in the large and expensive histories, and some facts which even they do not contain.

ANNALS OF MEDICAL HISTORY

The March number of the *Annals of Medical History*¹ contains ten contributions by writers other than the editorial staff, and includes the third instalment of Dr. Silvette's interesting study of the "Doctor on the Stage" during the seventeenth century, it is generously supplied with quotations from contemporary dramatists and there is much about quacks. Dr. Olmsted gives a full account of the posthumously published notes made by Claude Bernard on Pasteur's work on spontaneous generation. Bernard and Pasteur were firm friends and Bernard had never mentioned his criticisms to Pasteur, intending so Dr. Olmsted considers to test the matter fully before any action was taken. Bernard's death prevented this experimentation, and there is not any evidence that he would have allowed their publication. Sir Robert Armstrong-Jones contributes an attractive article on Keats's visit to Scotland in 1818. Dr. J. B. Penfold's analysis of the early history of scrotal elephantiasis shows the rather surprising result that in spite of no anaesthesia or antiseptics the operative mortality was not more than 20 per cent. one terrible operation, however, went on for eight hours. Dr. A. Randall recalls the last major operation performed by Philip Syng Physick, the Father of American Surgery—namely the removal of more than a thousand calculi from the bladder of the Chief Justice of America aged 76 with complete success. In a short note Dr. Thorington describes the iron votive offerings of St. Leonhard the saint of prisoners who died in the middle of the sixth century. A comparative study of medicine among the ancient races of Egypt, Babylonia and Assyria is contributed by Dr. P. J. Moorad. Dr. C. R. Hall writes on doctors and medical practice in the early days of Nassau County, New York, and Mr. J. W. Draper critically discusses the melancholia of Hamlet.

THE MOTHER AND THE HOME

It has devolved upon members of the Charity Organisation Society to collect material from this country for the approaching International Congress, dealing with "La Mère au Foyer," to be held in Paris. The greater part of the April issue of the organization's quarterly journal¹ is devoted to this subject. Under the general heading "Mothers of Britain. Estimates of their Efficiency," the question is reviewed from the angle of the C.O.S. family case worker and of the doctor, each of whom, through the exceptional opportunities afforded by their daily work, is well qualified to express an opinion. The views of statesmen, administrators, and academic exponents are also given, but the journal rightly allots comparatively little space to the information received from these sources. At a time when the medical profession is not perhaps at the height of its popularity with the general public it is gratifying to read that "our earthly providences are our mother and our doctor," and that "it is essential to our well-being that they work for us in close alliance." The family case-worker is aptly designated as the handmaid of both. The information required for the congress at Paris is indicated by questionnaires which are exceedingly and perhaps unnecessarily comprehensive. If the mother goes out to work, what is the effect on the family budget, the family health, the education of the children, and the atmosphere of the home? What is the proportion of (a) divorces and desertions, (b) child delinquents (1) when the mother did not go out to work and (2) when the mother did go out to work? These are only two comparatively simple examples from a host of questions framed to probe every aspect and ramification of a mother's life. The problem is further complicated by the varying conditions of life observable in different parts of the country, in addition to the wide differences of character and mental outlook in individual homes. In dealing with the information elicited the *Charity Organisation Quarterly* takes the sound view that more is to be learned from a few representative accurate case studies by capable workers than from a large number handled in a purely arithmetical manner.

¹ *Charity Organisation Quarterly*, April 1937 11 No 2.

"We come at last to the all-important question, What are the medical profession saying and doing about the mother in her home?" Evidently the writers have gone to considerable trouble to find out. In addition to a selection of replies by doctors, to whom the questionnaire was addressed, a number of extracts bearing on the subject are reprinted, with full acknowledgement, from articles in the *British Medical Journal*. Nutrition, child guidance, practical psychology, endocrine difficulties, and the menopause are some of the questions rightly included as relevant. But although it is difficult to see the wood for the trees the main theme appears to be the question whether a mother should work or stay at home. Provided that pregnancy is safeguarded, that an adequate alternative to maternal supervision is available for the children, and that the mother's employment does not take the form of heavy manual labour, the general consensus of opinion appears to be in favour of work. With small families housekeeping is not a whole-time job and the beneficial effect of outside interests for the mother, together with the improvement in material living conditions for the family provided by her earnings, are points adduced in support of this view. Whether engaged in outside work or not, it is clear that for a proportion of mothers, at any rate in the humbler walks of life, a certain amount of guidance and help is desirable. This, it is suggested, can best be supplied, not through leaflets, lectures, and regulations, but through the sympathetic personal contact, in their respective spheres of influence, of the family case-worker and the general practitioner.

ACTION OF ACETYLCHOLINE ON THE CENTRAL NERVOUS SYSTEM

In a classical research Feldberg and Gaddum¹ proved that acetylcholine is liberated at the terminals of pre-ganglionic fibres round ganglion cells, and suggested that acetylcholine is the normal transmitter of the nerve impulse at these junctions in the autonomic nervous system. This work has naturally led to fresh speculation as to the means by which impulses are transmitted at the synapses of the central nervous system. Conditions in the central nervous system are, however, far more complex than in peripheral ganglia, especially in the fact that in the latter no process corresponding to central inhibition normally occurs. A number of workers have examined the action of acetylcholine on different parts of the central nervous system. Dikshit² showed that, injected into the cerebral

¹ *J. Physiol.* 1934 81 305

² *Ibid.*, 1934 80 409 1935 83 42 P

ventricles of the cat, it depresses or abolishes respiration and produces a condition resembling natural sleep. Henderson and Wilson² observed that eserine or acetylcholine, when injected into the lateral ventricle in man, gave rise to similar effects—nausea, vomiting, increased intestinal movements, and sweating—but the circulation and respiration were unaffected. Schweitzer and Samson Wright¹ in a recent paper have examined the action of eserine and related substances and of acetylcholine on the knee-jerk of cats under chloralose anaesthesia. Eserine was found to increase the knee-jerk markedly and to heighten general reflex excitability, larger doses of the drug are followed by convulsions resembling those produced by the administration of strychnine. A detailed analysis showed that the excitatory action of eserine on reflexes is not due to changes in the blood pressure or respiration, and depends only in part on the well-known action of eserine of increasing the response of skeletal muscle to motor nerve stimulation. For instance, eserine enhances somatic reflexes in animals under deep ether anaesthesia, in which state the peripheral potentiating action of eserine on skeletal muscle is absent. Additional evidence was obtained from experiments in which the hind limbs were artificially perfused or had their circulation occluded, under these conditions the injection of eserine into the jugular vein still enhances reflex actions, although the drug cannot reach the periphery. It was concluded, therefore, that eserine stimulates the central nervous system, heightening reflex responses. The effects were equally well seen in decerebrate animals—proving that eserine is not merely anti-anaesthetic—and after transection of the spinal cord in the mid thoracic region—showing that the drug acts directly on the lower spinal somatic centres.

It is well known that the effects of eserine on the autonomic nervous system are identical in almost every respect with those of injected acetylcholine. Schweitzer and Wright's experiments with eserine naturally led them to investigate the action of acetylcholine on the central nervous system as they supposed that the results of administering eserine might be due to its anti-cholinesterase action retarding the destruction of normally formed acetylcholine. It was found however contrary to expectation, that acetylcholine unlike eserine usually depressed reflex responses. This effect is annulled by atropine but subsequent injection of larger doses of acetylcholine may still lead to the usual inhibiting effect. Evidence was presented that the inhibition is independent of changes

in circulation, respiration, or in the response of the muscle to motor nerve stimulation, and is due to some action on the central nervous system. The inhibitory action of acetylcholine is, however, intensified by the previous administration of small doses of eserine. To explain these rather unexpected findings further experiments were carried out with other drugs of the eserine series, which, like it, are anti-cholinesterases—that is they inhibit the action of the enzyme (cholinesterase) which normally destroys acetylcholine. Two of these substances, including prostigmine, were examined and found to depress reflexes, in part at all events, owing to an action on the central nervous system. As this result is similar to that of injected acetylcholine the authors suggest that this central inhibition may be explained by an anti-cholinesterase action of the drugs. This means of course that the central excitatory effect of eserine previously described must be brought about by some entirely independent mechanism. Schweitzer and Wright also mention that in preliminary experiments they have found that acetylcholine and prostigmine can abolish the convulsions induced by strychnine.

The authors are cautious in interpreting their results, and wish at this stage only to draw attention to the pharmacological aspect of their researches. It is natural, however, to see in this work the possibility that in the future we may have to consider that acetylcholine or related substances are concerned in an intimate manner with transmission of the nerve impulse in the central nervous system. But even if further inquiry establishes this hypothesis on a sound foundation it will not necessarily follow that naturally released acetylcholine acts, like the artificially injected drug as a depressing or inhibiting agent. With many drugs the route of introduction and the dose employed profoundly influence not only the extent but even the direction of the effect. As was pointed out previously in these columns,³ acetylcholine itself provides a salutary warning. Under certain conditions it causes vigorous repetitive contraction of skeletal muscle, while under slightly different circumstances it may have exactly the opposite effect—namely a curari-like paralysis. A preliminary note by Kremer Pearson and Wright⁴ extends these studies further, and describes observations on patients suffering from hemiplegia in whom small doses of prostigmine were injected into the cerebro-spinal fluid by lumbar puncture. The drug diminished or abolished muscle tone and reflexes like the knee jerk and ankle-jerk and had striking though

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 29 1937

THE CAPITATION FEE COURT OF INQUIRY INTO REMUNERATION OF INSURANCE PRACTITIONERS

The Court of Inquiry set up by the Minister of Health and the Secretary of State for Scotland and presided over by Lord Amulree began its deliberations on the morning of Wednesday May 26. The Ministry of Health and the Insurance Acts Committee of the British Medical Association exchanged Memorandums of Evidence on May 11 and exchanged Rejoinders on May 24. These four documents are given below with the exception of a non-controversial description of the machinery devised for the administration of medical benefit which was included in the Ministry's Memorandum.

MEMORANDUM BY INSURANCE ACTS COMMITTEE OF B M A

1 The Insurance Acts Committee of the British Medical Association believing the present rate of remuneration of insurance practitioners under the National Health Insurance Acts to have become inadequate, submits the following memorandum

History

2 In 1920 the annual capitation fee payable to insurance practitioners was fixed by a Board of Arbitration at 11s. In 1922 the medical profession accepted, on the grounds of the imperative necessity for national economy, the reduced rate of 9s 6d. In 1924 the rate of remuneration was fixed by a Court of Inquiry at 9s a rate which has been in operation since that year, with the exception of the period from October, 1931 to June 1934, when a voluntary deduction of 10 per cent was in operation and the period from July 1934 to June 1935, when a voluntary deduction of 5 per cent obtained. Although the rate fixed by the Court of Inquiry in 1924 was not regarded by the bulk of the profession as adequate, it was, of course loyally accepted. In these circumstances the Insurance Acts Committee does not propose to restate the case as presented to that Court of Inquiry but to confine itself to the changes relevant to the issue which have been manifest since that decision was made.

3 In the Committee's view the National Health Insurance system providing as it does for free choice of doctor and patient and eliminating direct payment to the doctor at the time of sickness is the best means of providing medical attendance and treatment for the lower paid workers of the country. This consideration has led the Committee to take the broadest possible view of the doctors' responsibilities, and continuously to focus its efforts on improving the value and widening the scope of the service rendered. As new methods of treatment and diagnosis have been perfected, the Committee has urged their acceptance as coming within the terms of service without raising the question of additional remuneration. Not without justice it has taken pride in the efficiency of the service rendered by insurance practitioners. To give examples of this attitude it may be stated that the Committee has co-operated in a general overhaul of the disciplinary machinery particularly in relation to medical certification and the keeping of medical records. It has co-operated in improving the machinery for investigating alleged excessive prescribing and has at its own expense, prepared and issued a *National Formulary* which has led to improved and economic prescribing. It has co-operated

with approved societies in a general overhaul of the certification procedure with a view to solving the problem of increased claims for sickness and disablement benefits, and to smoother working as between the doctors and those who administer sickness benefit. It has introduced at the expense of insurance practitioners a scheme for the retirement on pension of aged and infirm insurance practitioners whose means are straitened and against whom complaints may, because of their age and infirmity, arise. It has co-operated in the arrangement of lectures on national health insurance matters to final-year medical students, and initiated a voluntary scheme of superannuation, disablement, and family provision for insurance practitioners. Throughout it has been actuated by the desire to place at the disposal of the insured person an improved and improving service.

Some Testimonies

4 Before passing to the detailed presentation of the Insurance Acts Committee's case it is desired to draw attention to the testimony to the increased efficiency of the insurance service which has appeared in the annual reports of the Chief Medical Officer of the Ministry of Health.

1932 It is gratifying to be able to say that the experience of these officers [Regional Medical Officers] indicates clearly that, except in the case of a small minority of practitioners the standard of the medical service given to insured persons is not only high but is steadily advancing while the service with its capitation payment allows the practitioner to give and the patient to receive effective medical advice without the embarrassment of an impending bill and it may be added without the former disadvantages of contract practice.

1933 The importance of the service to the national endeavour towards raising the level of the health of the people as a whole and increasing the value of the life and capacity of each citizen can scarcely be over-estimated. The medical practitioners who provide the service by virtue of their opportunities for the early detection of disease in the individual form the first line of defence against communal disease and they provide also in most cases the best instrument for the prompt application to individuals of those preventive measures and improved methods of treatment which science puts at our disposal.

"The year 1933 saw the coming of age of the service and on appropriate occasions during the year much was said in celebration of the event by public men who had been or were concerned with the origin of the scheme in its various

aspects These utterances showed remarkable unanimity in their praise of what the service has accomplished. No one suggested that the scheme was or is immune from criticism or incapable of improvement. No human scheme is, and nowhere is the need for the application of every energy towards steady improvement recognized more clearly than among those directly concerned in administering and working the scheme. But no public speaker proposed that insurance should be stopped or curtailed and no one had the least doubt that the medical service given to the insured population to-day is not only vastly superior to the service given to the same class of people before the introduction of national health insurance but that the improvement since its inception has been steady and continuous.

1935 The Insurance Medical Service rightly, therefore, takes its place as one of the most effective branches of the public health service.

"The smoothness of the working of this vast scheme may be regarded as generally recognized. On a conservative estimate, in each year 8 000 000 insured persons seek medical advice and over 50 000 000 attendances are given by the doctors. In these circumstances it is remarkable that during 1935 in only 157 cases was it necessary to investigate a complaint regarding the adequacy of the service and in only 48 of these were the facts held to justify the imposition of a penalty. In addition to this negative evidence from the paucity of the number of complaints there is also ample positive testimony from competent observers to the success of the Insurance Medical Service. The vast majority of insurance practitioners interpret the terms of their contract in no niggardly spirit and undoubtedly the standard of the service they give is not only high, but is yearly rising as fresh advances of medical science add to the general practitioners' armamentarium in diagnosis and treatment. In this connexion it is significant that the interest shown by practitioners in post graduate study courses is steadily growing, and every year more practitioners feel impelled to devote part of their hard-earned leisure to attending the refresher courses of study increasingly provided by many of the medical schools throughout the country.

It is no less gratifying to note that the general improvement in the efficiency of the service is recognized by other leading authorities on national health insurance. In an address to the Annual Conference of the National Federation of Employees Approved Societies in March, 1933, the president (Mr Henry Lesser) said:

Whatever individual lapses there may be—and these are relatively very few—little complaint is heard from insured persons in regard to the treatment they receive from the doctors of their choice."

In his address at the National Conference of Industrial Assurance Approved Societies' Annual Meeting in December, 1934, the president (Sir Thomas Neill) said:

Before leaving this subject I should like to pay tribute to the practitioners on the Insurance Acts Committee for their co-operation and their obviously sincere desire to do everything in their power to ensure that the National Health Insurance Act shall be administered in the best interests of the insured population."

In 1934 the Secretary of the Welsh Board of Health, a civil servant of wide experience, said in a public speech that:

It was the fashion in some quarters to disparage the quality of the service given to insured persons whereas taking the wide view it was a very satisfactory service.

The report of the Departmental Committee on Scottish Health Services issued in 1936 says of national health insurance:

The evidence submitted to us from all quarters points to the success of the medical service under the national health insurance scheme."

General Considerations

5 There are certain general considerations of profound importance. The last twenty years and more particularly the last ten have been characterized by a reorientation of medical thought and a widening of the basis of medical

practice. Whereas, until comparatively recently, modern medicine found its sanction to a large extent in the sciences of pathology and morbid anatomy it now approaches the problems of health and disease from the standpoint of applied biology, concentrating not only on the causes and treatment of disease in its individual manifestations, but on the promotion and maintenance of positive health, viewing the individual less as a vehicle of disease processes and more as a living organism adapting itself to its environment. This change is admirably expressed in a paragraph of the report of the Departmental Committee on Scottish Health Services, 1936:

470 It will be noted that in the modern conception of medical practice great emphasis is placed on the role of the family doctor as health adviser. Owing to the advances of scientific knowledge many specialisms have developed and there is nothing to suggest that this movement will be less rapid in the future than it has been in recent times. On the other hand there has emerged a growing public appreciation of the value of health and of the importance of early attention to departures from normal and a demand for the services of the general practitioner as health adviser. We think that this movement also is bound to develop rapidly and that national policy for the promotion of the health of the people should be so framed as to encourage it. It appears to us that the role of health adviser by the family doctor is a natural development of ordinary medical practice and that the training of the student of medicine should be adapted to fit him for it.

6 Inevitably this change has found expression in the work of insurance practitioners. To their responsibility for the diagnosis and treatment of cases of individual sickness, which is certainly no less than it was, has been added an increasing measure of responsibility for the prevention of disease in the normal person and for the correction of minor departures from the normal. Although as a result of this preventive work the actual sickness incidence may be expected to decrease, there are involved responsibility and skill which find but partial expression in an increase in the number of items of service rendered. It will be agreed that it is of the greatest importance that the insurance practitioner should be encouraged to exercise to the full his opportunities to advise in the early stages of disease in order that so far as possible, serious disease may be prevented and the patient restored to health with a minimum loss of time.

7 There has been an increase in the complexity and effectiveness of insurance practitioners' work as a result of improvement in and elaboration of methods of diagnosis and treatment. For example advances in the knowledge of pernicious anaemia have led to more complicated methods of diagnosis and more laborious methods of treatment. There has been a relatively large increase in the incidence of some diseases and new types of other diseases have emerged. For example, the proportion of persons treated for ulceration of the stomach and duodenum has grown considerably in recent years, involving on the part of the doctor in attendance unremitting care often over prolonged periods. There has been a change in the medical outlook on the diagnosis and treatment of many conditions of which psychological troubles may be given as an example. These disturbing conditions, which are becoming more prevalent with the increased stress of modern life, make heavy demands upon insurance practitioners who, because of their intimate knowledge of the domestic and other circumstances of their patients are peculiarly well situated to deal with them.

8 Modern methods of diagnosis and treatment have increased the time which an insurance practitioner spends in the examination of individual patients. There may be given as examples the use of the sphygmomanometer as a routine method of diagnosis, the use of sera and vaccines for intramuscular, intradermal and subcutaneous injection, the use of sclerosing methods, the treatment of varicose veins and varicose ulceration, the collection of material for biological and bacterial investigation, an

increasing resort to psychological treatment, and the more prolonged and complete ante natal examinations undertaken as a routine to-day. The insurance practitioner spends a larger proportion of his working day with his insured patients than he did prior to 1924.

An Ageing Population

9 The proportion of elderly people for whose medical attention insurance practitioners are responsible is, coincident with the increasing average age of the population, growing with some rapidity. In 1928 the number of in-

mittee Practitioners in almost every Insurance Committee area have responded, and the number of insured persons in this sample has during each of the last six years been approximately 1½ millions. There have been constant changes in the personnel of the doctors keeping these records, and the total number of practices examined for one or more years is over 3,000. Thus the Insurance Acts Committee is now able to produce a volume of statistics in which it places complete confidence. The following is an analysis of the statistics collected in respect of 1922 and during the past seven years.

	1922	1930	1931	1932	1933	1934	1935	1936
Number of Insured Persons	665 118	1 111 041	1 603 152	1 757 980	1 583 102	1 474 373	1 641 208	1 590 207
Attendances at Surgery	1 837 334	3 940 578	5 547 691	6 558 709	6 151 399	5 423 923	6 195 788	6 054 268
Visits	663 262	1 364 539	2 069 283	2 256 777	2 229 495	1 920 496	2 195 869	2 115 992
Average Attendances at Surgery	2.76	3.54	3.46	3.73	3.88	3.68	3.77	3.80
Average Visits	0.99	1.22	1.29	1.28	1.40	1.30	1.34	1.33
Average A's and V's (combined)	3.75	4.77	4.75	5.01	5.29	4.98	5.11	5.13

sured persons over 65 was 873,800 and in 1935 it was 1,257,300. Expressed as percentages of the whole insured population, this means that persons over 65 represented 4.98 per cent of that population in 1928 and 6.7 per cent in 1935. An important contributory factor in lengthening life is the constant medical attention they have been able to command, and in turn older people require more medical treatment. Some of these people, such as those suffering from diabetes and pernicious anaemia, are enabled to live only because they receive, and only so long as they receive, continuous and active medical treatment.

Statistical Evidence

10 It is recognized that the general submissions of the Insurance Acts Committee in regard to the reorientation of medical thought, the increased attention to the preventive aspects of disease, the increased complexity and effectiveness of modern methods of diagnosis and treatment and the increased time devoted to individual patients are incapable of precise expression in statistical form. It is believed that unmistakable evidence of this increase in work and responsibility readily presents itself to all who observe the development of medical thought and the relation of that development to a progressive public opinion. Indeed public opinion and governmental action have to a considerable extent stimulated these developments. Confirmation of the Committee's submissions is, however, found in the statistics which have been obtained regarding the number of items of service actually rendered by insurance practitioners to their insured patients.

11 It was contended by the Committee's witnesses before the Court of Inquiry in 1924 that the figures then submitted involved an understatement of the volume of work which insurance practitioners were called upon to do. The Ministry's estimate at that time of the average number of items of service rendered to each insured person on a doctor's list was 3.5 per annum while the Insurance Acts Committee's estimate was 3.75 per annum. The Committee's figure was based upon statistics supplied by a large number of insurance practitioners obtained by counting the items of service recorded on the official medical record cards in their possession at the end of the year 1922. These figures did not take into account services rendered to persons whose record cards had gone from their possession by reason of change of address, death or cessation of title to benefit.

12 Following that inquiry the Committee decided that in order to obtain an accurate quantitative estimate of the amount of work undertaken by insurance practitioners it was necessary to secure a meticulous daily record of work done by a substantial proportion of them. Each year since 1924 every Panel Committee has been asked to find 10 per cent of its constituents who would be willing to keep day by day records on cards supplied by the Com-

Summarized, these statistics (1930-6) show

- That the average number of consultations at surgery is 3.705 per insured person
- That the average number of visits to patients' homes is 1.315 per insured person
- That the average number of attendances and visits (combined) is 5.02 per insured person

13 Although there has been a concerted effort by the Insurance Acts Committee and approved societies to reduce the number of patients referred to regional medical officers, the number of reports furnished to these officers has greatly increased. According to the Annual Reports of the Ministry of Health and Department of Health for Scotland, the number of references of this kind to regional medical officers in the year 1923 was 165,636, while in 1935 it had become 524,430. The work involved is only partly reflected in the statistics relating to the number of items of service rendered.

Practice Expenses

14 On the occasion of the last Court of Inquiry it was accepted that the ratio of practice expenses to the total income in non-dispensing insurance practice was 25 per cent, while the ratio in dispensing insurance practice was 33½ per cent. Since that date information upon this point has been collected by the Committee and the statistics now available show that in non-dispensing insurance practice the ratio is on average 30 per cent, while that for dispensing insurance practice has increased to 36 per cent. Rates, taxes, and the cost of employing assistants and locum tenens show an increase in comparison with 1924. The young medical practitioner without capital who, ten years ago would have become an assistant in general practice now finds that there are more attractive and remunerative avenues in other branches of medical practice. Consequently, higher salaries are now demanded by assistants.

Travelling Costs

15 For the proper conduct of medical practice a motor car is an absolute necessity. The public demands that medical aid in non-emergency as well as emergency conditions shall be made available in the shortest possible time, rendering the use of a motor car in the visiting of patients inevitable. It should be remembered that a car of good appearance is not without its psychological value. A considerable number of medical practitioners maintain a second car so that at no time are they without an effective vehicle. The mileage involved in the attendance upon a given number of patients is rising a change which applies not only to those patients in respect of whom payment is made from the Mileage Fund but also to patients within the two mile radius in respect of whom no payment is made.

16 The 15 h.p. model is perhaps typical of the car most commonly employed in general practice, although,

of course, cars of greater or less horse power are not uncommonly used. The life of cars in common use to-day is shorter than that of cars in use in 1924, the depreciation is higher and second hand value bears no relation to the intrinsic value of a car at the time of sale.

17 The following comparative figures of costs for a 15 h.p. car have been obtained from the Automobile Association

Running Costs per mile

	1922-24	1936
Petrol (20 miles per gallon)	1 15d	0 96d.
Lubricants	0 14d	0 12d
* Insurance	0 36d	0 36d
† Vehicle Tax	0 36d.	0 27d
Repairs and Replacements	0 19d	0 16d
Tyre Repairs and Replacements	0 40d	0 32d.
‡ Garage—Cleaning and Miscellaneous	1 20d	1 08d
‡ Depreciation on Cost of Car	0 96d.	1 24d.
	4 76d	4 45d.†

* Allowance has not been made for increased rates operating in certain congested areas—for example London, Glasgow and parts of Lancashire.

† Standing charges which do not vary in total amount with mileage.

‡ Increase in the cost of petrol in 1937 would raise this figure to 4.52d.

It may be stated in general terms that doctors have experienced little decrease in the costs of motoring since 1924.

Post Graduate Instruction

18 Nor must the need for post graduate instruction be forgotten, for it has become an indispensable feature of medical life. Every practitioner desirous of keeping himself abreast of medical science must resort from time to time to his medical school or to a neighbouring hospital centre where he can avail himself of facilities for post-graduate study. The remuneration a practitioner receives for his services should be sufficient to enable him to make provision for a periodical 'refresher' course.

Cost of Living

19 It will be recollected that the Insurance Acts Committee submitted as part of its case before the Court of Inquiry in 1924 a memorandum by Professor A. L. Bowley (late Professor of Statistics in the London University and Lecturer at the London School of Economics and Political Science) on the statistical aspects of insurance practice, which was then accepted as an accurate and impartial survey. The Committee has again approached Professor Bowley and attached to this memorandum is an Appendix prepared by him, which contains statistics relating to the cost of living in a typical middle-class household, with special reference to that of a medical practitioner. The data have been arranged for the years 1924 and 1936 and indicate a fall of between 7 and 10 per cent in the cost of living of a doctor's household instead of 13 to 14 per cent shown by the Ministry of Labour's Index. The diminution is due to the different proportions of income allotted to the classes of expenditure and to the assumption that some items of expenditure have not changed. It is also of importance to note that the allotment of expenditure (questioned on the occasion of the last award) calculated by Professor Bowley as appropriate to the budget of a middle-class family has proved to be similar to that published by Professor C. Jones in the *Journal of the Royal Statistical Society* 1928, p. 463.

The Young Adolescent

20 Under legislation shortly to be introduced medical benefit is to be extended to a new age group consisting of young persons under 16 years of age and in insurable occupations. These young adolescents will receive a full general practitioner service although as they will not be entitled to cash or sickness benefit no certification for national health insurance purposes will be required of insurance practitioners. Had certification been required of insurance practitioners for these entrants to national health insurance it would not of itself have proved a serious burden. The responsibility of the insurance practitioner in respect of these persons will be to a not inconsiderable

extent preventive and advisory. He will be concerned less with incapacity than with positive instruction in health and in the early detection and treatment of disease. Further, although he will not actually fill in national health insurance certificates, the responsibility for deciding whether incapacity exists will be imposed upon the practitioner. The employer, for example will almost certainly require a decision on this point.

21 It is not now disputed that one general capitation rate should apply to all insured persons including those shortly to be brought into medical benefit. If as is anticipated, the number of young adolescents in this new group proves to be one million they will form a little over 5 per cent of the new insured population. The absence of the requirement to fill in official national health insurance certificates in the case of 5 per cent of the insured population, a group in which the responsibility would be predominantly preventive and advisory does not justify any lowering of the general capitation rate.

Conclusion

22. If the 9s. of 1924 was a fair award for the number of items of service then undertaken (3.75 in 1923) the annual capitation fee on the basis of the existing number of items of service (five on average in the last seven years) should now be 12s. Admittedly the cost of living has fallen during that period, though not for the doctor to the extent suggested by the official index. The application of the cost of living figures justifies the request that the capitation fee taking into account these two factors alone should be 11s. 1d. But this is not to take into account such general considerations as increased responsibility the widened scope of medical practice, the increased time spent on individual patients, the increased ratio of costs to income and the almost certain prospect of a rise in the cost of living. In all the circumstances the Insurance Acts Committee submits that an annual capitation fee of 12s. 6d. should be paid to the insurance practitioner for every insured worker in medical benefit including those between the school-leaving age and 16 years of age for whom the Government intend to make medical benefit available.

APPENDIX

MEMORANDUM BY PROFESSOR A. L. BOWLEY, Sc.D., F.S.S.

I Cost of Living

The Ministry of Labour Cost of Living Index at certain dates is

July, 1914	100
July, 1923	169
July, 1924	170
July, 1936	146

In connexion with the British Medical Association's case to the Court of Inquiry in 1924 I prepared the following table of estimated annual expenditure of an average doctor's family—man, wife, 21 children, 26 servants (p. 317).

It will be seen that the change in annual expenditure for a doctor's family from 1913-14 to 1923 was estimated as being in the proportion 100:157. The latter figure (157) was lower than that of the Ministry of Labour (169) because some reduction was assumed in the quantities purchased of foods whose prices had then risen most; a smaller increase in the price of clothes, and a larger proportion of expenditure on sundries and personal requirements with a relatively small increase in price. The allotment of expenditure estimated in the above table has proved to be very similar to that found by Professor C. Jones for middle-class families in the *Journal of the Royal Statistical Society* 1928, p. 463.

	1913 or 1914	January 1920		July 1923	
		Percentage Increase over 1914	Total	Percentage Increase over 1914	Total
	£		£		£
Food	188	81½	341	48	278
Laundry	24	100	48	75	42
Wages	58	43	83	43	83
Two-thirds rent	48	0	48	30	62
Two-thirds rates	14	37	19	40	20
Two-thirds fuel and light	20	63	33	80	36
Clothes	90	100	180	100	180
Education fees	35	15	40	50	52
Education boarding	35	50	53	22	43
Postage	6	50	9	50	9
Tobacco	6	100	12	100	12
Drinks	10	100	20	100	20
Holidays	36	50	54	50	54
Sundries— Household	30	75	53	85	55
Personal	70	50	105	50	105
Total	670		1 098		1 051
Relative numbers Labour Gazette	100		164		157
	100		225		169

There are several methods of estimating the fall in prices from 1923-4 to 1936 but as they all lead to nearly the same result it is not necessary to follow them in much detail.

If the doctor's budget for 1914 is re-priced for July 1936, it shows an increase of 46 per cent—precisely the same as for the Ministry of Labour's working-class budget. This result indicates that while the rise was less for doctors than for the working class between 1913-14 and 1923-4 the fall has also been less between 1923-4 and 1936. In other words there was a rise in the ratio of 100 to 157 (57 per cent.) in the first period and a fall in the ratio of 157 to 146 (7 per cent.) in the second period.

Another method of assessing the fall in the cost of living of a doctor's family is by an examination of the rise or fall in the cost of the various items in the Ministry of Labour index numbers and the doctor's budget.

Ministry of Labour Index Numbers

	July 1923	% fall or rise	July 1936
Food	162	—20	129
Rent	147	+ 8	159
Clothing	220	—13½	190
Fuel and light	182	—5	170-175
Miscellaneous	185	— 8	170
All items	169	—13½	146

Doctor's Budget	1923 £	% fall	1936 £
Food	278	12	245
Laundry and wages	125	—	125
Rent and rates	82	—	82
Fuel and light	36	5	34
Clothing	180	13½	154
Education, postage tobacco drinks, holidays	190	—	190
Sundries	160	8	147
	1 051		977

It will be seen that the doctor's budget shows a reduction of £74 on £1,051, or 7 per cent. If however, the full allowance is made of 20 per cent for food (as shown in the Ministry of Labour index numbers), instead of the smaller reduction of 12 per cent. due to the presumed economy in expensive foods in 1923 the reduction is £105 on £1,051 or 10 per cent.

Without pursuing other methods, therefore the reduction in the doctor's budget can be assessed at 8 per cent.—the mean of the two methods illustrated. This reduction is less than that shown by the Ministry of Labour principally because of the items assumed to be unchanged in a doctor's budget and because food is a smaller proportion of the doctor's budget than of the working-class budget.

II The Doctor's Capitation Fee and the Cost of Living

To the 7s 3d of 1914 corresponds 7s 3d × 1.46 = 10s 7d now

To the 9s of 1924 corresponds 9s × 1.46 = 13s 4d last July but 9s × 1.46 = 13s 4d on the Ministry of Labour index. The former reckoning is to be preferred for reasons given.

Prices of food and fuel have risen since July, 1936 but if this is considered to be the normal seasonal increase attention ought not to be paid to it for comparison with previous July figures. It would raise the equivalents by about 2d.

The two index numbers for 1920 are given in the table quoted above as 225 for Ministry of Labour and 164 for the doctor's budget. The present equivalents of 11s in 1920 are about 7s 2d for the former and 9s 7d for the doctor's budget.

On the assumption that the claim for increased remuneration is based upon the increase in attendances per insured person on a doctor's list—5.11 in 1935 compared with 3.75 in 1923—the equivalents raised in proportion become

	Official Index 1924	Doctor's Budget 1924
7s. 3d. in 1914	14 4	14 4
11s. in 1920	9 9	13 4
9s. in 1924	10 6	11 4

MEMORANDUM BY THE MINISTER OF HEALTH AND THE SECRETARY OF STATE FOR SCOTLAND

Basis of Determining Remuneration of Insurance Practitioners

1 The present capitation fee of 9s was fixed on the recommendation of a Court of Inquiry in February 1924, after exhaustive examination, and it follows from the terms of reference to the present court that the award of the 1924 court is to be taken as the starting point of the inquiry as representing the proper and adequate remuneration at that time for the treatment of insured persons. The only points therefore to consider are the changes that have taken place since 1924, and the effect (if any) that such changes should have on the capitation rate.

2 The changes that have occurred since 1924 may be considered under four heads

- (1) The fall in the cost of living
- (2) The fall in the expenses of a doctor's practice
- (3) The variation of (a) the number and (b) the nature

of the services that insurance doctors are called upon to render to their insured patients

(4) The proposed extension of insurance to juveniles

3 As a preliminary it may be remarked that the number of insurance practitioners has since 1924 increased in greater proportion than the number of insured persons

GREAT BRITAIN			
	1924	1936	Increase per cent.
Number of insured persons entitled to medical benefit	15,346,000	18,245,000	18
Number of doctors under contract with Insurance Committees	15,725	20,112	28

While this increase in the number of insurance doctors in relation to the number of insured persons might be held to indicate that the service had become increasingly attractive it is realized that factors other than remuneration are involved.

The four changes mentioned are now considered in detail

Fall in the Cost of Living

4 A factor to be considered in determining the adequacy of a rate of remuneration is its real value in terms of commodities, and in the last arbitration on the doctors' capitation fee, in 1924, both parties based arguments on the variation in the cost of living since the last determination of the fee. It was common ground that the Ministry of Labour index figure could not be applied without adjustment. It was submitted that the proper course was to consider what change had taken place in the remuneration of other professions. In most other professions, however, the issue was complicated not only by the fact that the necessary data were not readily available but also by the fact that fees charged took account of an allowance for clerical and technical assistance of various kinds as well as the remuneration of the principal. The Minister therefore suggested a comparison with appropriate grades of the Civil Service, since in his view the higher ranks of the Civil Service formed, broadly speaking, the only comparable body of salaried professional men for whom the ratio of post war increase in remuneration could be determined with any exactness. It is not known what weight was attached to such arguments by the court of 1924, but in order to assist the court in considering this aspect of the question, which in the Minister's view is important because of the substantial fall since 1924 in the cost of living as measured by the Ministry of Labour Index Figure, an explanation is given below of the method of dealing in the payment of the Civil Service with post-war changes in the value of money.

5 Not only are the higher grades of the Civil Service the only professional class for which exact information is readily available as to the effect on remuneration of post war changes in the value of money, but there is a further argument for using the Civil Service scale as a measure of the adequacy of the remuneration of insurance practitioners. The latter are not, in the strict sense, public servants, but in so far as they are paid out of public or statutory funds their position is analogous to that of public servants and the Government could not in equity treat them differently in respect of variations in the cost of living unless they were satisfied that new considerations had arisen since 1924 which would necessitate special measures to attract and retain general practitioners in the numbers and of the type requisite for the provision of an efficient service. The figures given in paragraph 3 of this part of the Memorandum show that this condition for special treatment is not satisfied. Moreover the fact that so long as they observe the conditions of their contract medical practitioners who have joined the service have a right to remain in it is another feature which makes their position comparable with that of civil servants.

6 It should be explained that the scale used in adapting Civil Service salaries for the post war increase in the cost of living (which was also widely adopted by local authorities) allows war bonus at the full rate of the cost of living index figure in the case of the lowest paid officers only—that is those receiving salaries up to £91 per annum, for salaries beyond this point the rate of bonus was progressively reduced. For remuneration at the level with which the court will be concerned the bonus allowed in respect of increased cost of living was equivalent to a small part only of the increase represented by the Ministry of Labour Index Figure.

7 For the period March to September 1924 Civil Service bonus was calculated on a cost of living index figure of 80 per cent. above the level of July 1924. From October 1 1924 Civil Service salaries were consolidated on the basis of a cost of living index figure of 55. Since that date the cost of living index figure has been uniformly below 55.

8 The practical effect of the Civil Service scale is illustrated in the following table.

CIVIL SERVICE SALARIES

Basic Salary (1)	Salary at Index Figure 80 (1924) (2)	Salary at Index Figure 55 (1934) (3)	Percentage Increase of Col. 3 to Col. 1 (4)	Percentage Decrease of Col. 2 to Col. 3 (5)	9s. Scaled Down by Percentage in Col. 5 (6)
£ 750	976	905	21	7	8 4
800	1 023	954	19	7	8 4
850	1 085	1 011	19	7	8 4
900	1 130	1 058	18	6	8 5
950	1 191	1 115	17	6	8 5
1 000	1 234	1 161	16	6	8 5
1 050	1 294	1 218	16	6	8 5
1 100	1 336	1 262	15	6	8 5
1 150	1 395	1 318	15	6	8 5

9 The salary of a civil servant should however, be more properly compared with the net than with the gross income of an insurance doctor and the effect of the above table is therefore that, on the basis of comparison with Civil Service salaries, the fall in the cost of living since 1924 justifies a reduction in the net income of three-quarters of the amount by which the figures in the last column above fall short of 9s (on the assumption, adopted at the last Inquiry, that practice expenses on the average amount to one quarter of the total receipts). Throughout the range shown such a reduction varies from just under 4½d to just over 5½d, and on average it is submitted that there should be a reduction of slightly over 5d in that part of the 9s that is not absorbed by practice expenses.

Fall in the Expenses of a Doctor's Practice

10 The Minister has not detailed information as to the proportion of a doctor's gross income that is absorbed by practice expenses or the exact proportion of those expenses that is due to the cost of locomotion. It was stated at the Inquiry of 1924, on behalf of the Insurance Acts Committee, that practice expenses were about 25 per cent of the gross income, and the cost of locomotion has been variously estimated as from 75 to 85 per cent of the total expenses of practice. It is proposed to take the lower figure and to assume that the practice expenses were in 1924 25 per cent of the gross income and that cost of locomotion was about three quarters of the total practice expenses. That is, of a capitation fee of 9s., rather over 1s 8d represented in 1924 the cost of locomotion.

11 Since 1924 motoring costs have fallen considerably but the amount of the fall is not easy to estimate. The simplest comparative figures are the mileage rates allowed by the Treasury to such civil servants as necessarily use their own cars on official business and the conditions under which those cars are used do not appear to differ from those of travelling done in the course of an insurance practice sufficiently to invalidate the comparison. The rates per mile at the beginning of 1924 and those now in force are shown in the following table.

	7 h.p.	10-11 h.p.	Over 11 h.p.	
March, 1924	5½d	7d	8d.	
	7-8 h.p.	9-10 h.p.	11-12 h.p.	Over 12 h.p.
1937	2½d.	3½d.	4d	4½d.

It should be added that there was a small reduction later in 1924 and that the current rates were fixed in 1933. The latter have recently been reviewed and they are considered as still holding good.

From this comparison the reduction in motor travelling costs since 1924 would be nearly one half. These rates are not fixed arbitrarily by the Treasury but were arrived at after careful examination in consultation with representatives of the staffs affected.

12. An alternative method of estimating the fall in motoring costs is to construct a typical annual budget for 1924 and for the current year. The information on which

the table below has been prepared has been obtained from various sources, such as *The Motor Industry of Great Britain* published by the Society of Motor Manufacturers and Traders, *The Motor Car Index* published by Messrs Fletcher and Sons, Norwich which shows the prices of most models of cars in 1935 and earlier years current catalogues and information obtained for the investigation mentioned at the end of the preceding paragraph. The individual items are dealt with more fully in the notes that follow the table.

	1924	1937
	£ s. d.	£ s. d.
Cost of car (5 years' life)	48 12 0	28 16 0
Interest on capital expenditure	9 18 6	3 1 7
Tax	11 0 0	7 2 6
Tyres	13 10 8	6 7 9
Petrol	21 17 6	20 6 3
Maintenance	19 0 0	18 13 4
Garage	16 0 0	14 10 0
Insurance	12 17 6	12 2 6
	£152 16 2	£110 19 11

Notes—The Society of Motor Manufacturers and Traders, in its publication mentioned above, shows (p. 38) a reduction in the price of private cars of every make and horse power amounting to 50 per cent. between 1924 and 1935. The reduction takes account not only of changing prices of individual models, but of the greatly increased proportion of cars of lower nominal horse power among the total sales (p. 72). The sales apply to the public generally, and presumably therefore to insurance practitioners. The figures for 1937 are based on a car of 9-10 horse power costing £160; those for 1924 on a car of twice that price, and an annual mileage of 8,000 is assumed for both years.

A five years' life for the car has been assumed with a residual value of 24 per cent. in 1924 and of 10 per cent. in 1937. The first figure in each column is one fifth of the difference between the original cost and the residual value. Interest has been taken at 5 per cent. in 1924 and 3½ per cent. in 1937. Taxation was £1 per horse power in 1924 and 15s. in 1937. A small allowance has been made for the fact that the 1924 typical car was of rather higher nominal horse power. The expenditure on tyres is based on a life of 8,000 miles for covers and 12,000 for tubes in 1924 and 15,000 for covers and 20,000 for tubes in 1937. The cost for covers is taken as 61s. and 52s. 7d., and the cost for tubes as 10s. and 9s. 9d. respectively.

The prices for petrol ruling in 1924 averaged 1s. 9d. per gallon (disregarding the additional charge for petrol supplied in cans). The present price of No. 1 grade spirit is 1s. 7½d. per gallon. Thirty-two miles per gallon has been assumed for both years. The charge for maintenance includes washing and is based on figures agreed for the purposes of fixing the Civil Service mileage rates mentioned above. Allowing for the fall in nominal horse power of the typical car, there has been little change in the insurance premiums for full cover. No allowance has been made for a possible increase in the number of cars covered for third party risks only. The cost of garage varies so widely according to circumstances that any figures given must be speculative. Those shown above were agreed for the fixing of Civil Service mileage rates.

13 These figures show a reduction in motoring costs of 27 per cent. Figures have been obtained from a well known firm from whom cars can be obtained on hire and these show a reduction of approximately 30 per cent. in the present rates as compared with those for 1924. These figures taken together with the Civil Service mileage rates (para. 11) justify an assumption that the cost of locomotion has fallen since 1924 by not less than 30-40 per cent. Taking the mean figure this means that for every 1s. 8d. spent on locomotion in 1924 (see para. 10 above) the insurance practitioner need now spend 1s. 1d. only—a reduction of 7d. on the 9s. capitation fee.

Costs of travelling dealt with above have been taken as three-quarters of the total expenses of practice. The remaining items representing about 7d. out of the 9s. capita-

tion fee must, it is submitted, be presumed to have fallen approximately in proportion to the change in the value of money since 1924, but as the effect on the capitation fee would only be represented by something less than a penny it has not been taken expressly into account for the purposes of this memorandum.

Number of Services Rendered by Insurance Doctors

14 From time to time examinations have been made of the medical records held by insurance practitioners to ascertain the average number of services rendered to their insured patients. The method adopted for the examination made in 1925 (for the purposes of the Royal Commission on National Health Insurance then sitting) was to select in each region into which England and Wales is divided for the purposes of the Regional Medical Service an approximately equal number of doctors who were known to be good record keepers. In this way a representative sample of all types of practice—urban, semi-urban and rural, industrial, and residential—was secured. The examination was made in the spring of 1925 by the Regional Medical Officers and was confined to records of insured persons who were on the list of the selected doctors throughout the whole of 1924 and were still on those lists at the time the examination was made. The examination thus excluded the records of persons who (i) had transferred from one doctor's list to another during the year 1924, (ii) were new entrants into insurance and were placed on a doctor's list for the first time during the year (iii) had gone out of insurance (for causes other than death) or (iv) had died between the end of 1923 and the date of the examination. (The records relating to these last two classes were no longer in the possession of the doctors concerned.)

15 The survey has been repeated this year in relation to services rendered to insured persons during 1936. The 1925 survey covered 568 practices, this year's covered 660. The initial results of the surveys were as follows:

	1924			1936		
	Men	Women	Total	Men	Women	Total
Cards inspected	146,648	75,538	222,006	225,246	111,582	336,828
Percentage of cards bearing entries	43.1	44.4	43.7	50.5	55.4	52.1
Attendances recorded	376,662	204,168	580,790	620,169	356,226	976,395
Visits recorded	118,384	57,203	175,551	163,958	92,181	256,139
Total services recorded	494,970	261,371	756,341	784,127	448,407	1,232,534
Average number of attendances per card examined	2.57	2.71	2.62	2.75	3.19	2.90
Average number of visits per card examined	0.81	0.76	0.79	0.73	0.83	0.76
Average number of services per card examined	3.38	3.47	3.41	3.48	4.02	3.66

16 It was assumed in the calculations for 1924 that on average classes (i), (ii) and (iii) of the classes referred to in paragraph 14 would receive the same amount of medical attention as was given to the persons whose records were inspected, but that the records of persons who had died would show a greater number of visits and attendances. A separate examination was made in April 1925 of the records held by the Department of persons in class iv—that is, persons who had died during 1924 or after the end of the year but before the date of the examination. As anticipated these records disclosed a higher average of services than those dealt with in the main examination. A similar separate examination was made for 1936 in February and March of this year.

17 If the initial figures are corrected for the omission of dead records on the assumption of a death rate of 10 per 1,000 in each case the average number of services per card examined becomes 3.55 for 1924 and 3.72 for 1936, showing a true increase over the period of approximately

5 per cent. It will be observed that the proportionate correction for services on the cards of persons who died before the date of investigation was distinctly less in 1937 than in 1925, further reference will be made to this point later.

18 Comparing the uncorrected figures for 1924 and 1936 it will be seen that there has been an increase of 73 per cent in the average number of services rendered. At the same time there has been a slight shift in the balance of attendances and visits, the number of surgery attendances having increased by 10.7 per cent, while the average number of visits has fallen by 3.8 per cent.

How far this represents a net increase of work is not easy to determine. It is possible that it is the result of early recourse to the doctor. If this were the explanation the work would be lightened by increased opportunity of checking disease before it had progressed so far as to prevent the patient from visiting the doctor. A suggested method of estimating the net effect of the change is to weight the visits and attendances respectively in the ratio of 1½ to 1 (the average charge in private practice for a visit being usually about half as much again as the charge for an attendance). On this basis there would be on the uncorrected figures a net increase of work of about 6 per cent.

	1924	1936
Attendances	2.62	2.9
Visits × 1½	1.18	1.14
Total	3.8	4.04

If this weighting is applied to the figures corrected for the "dead" records the totals become 3.99 for 1924 and 4.12 for 1937 and the estimated net increase of work is about 3½ per cent. Applying this percentage to the capitation fee of 9s., the appropriate increase under this head is rather less than 4d.

19 The two essentials in an investigation of this kind are, of course, that the practices inspected should be a true sample and that the figure obtained should be properly comparable with those of the previous investigation. As to the first of these points the Insurance Acts Committee was furnished in 1925 with a copy of the instructions to the Regional Medical Staff concerned in the examination of the medical records. In a letter dated March 24 1925, the secretary of the Insurance Acts Committee stated, after consulting the chairman of that Committee, that they did not desire to take any exception to the instructions, and thought that the instructions would result in a fair sample being taken. Copies of the instructions for the latest survey (which follow closely the earlier instructions) are appended to this memorandum (Appendix II).

20 It will be seen from what is said above that care has also been taken that the figures deduced from the examinations of doctors' records in 1925 and 1937 should be truly comparable. A possible cause of error appeared to be shift of population since 1924 and this question was specially examined. In both 1924 and 1937 the number of records examined in Northern England and in South Wales where the demand on doctors' services is more marked than elsewhere was larger in proportion to the population of those districts than the number for the rest of the country. This excess of records for Northern England and for South Wales was more marked in 1937 than in 1925 and the resulting error is a slight exaggeration of the number of services given in 1936 as compared with 1924.

21 It is perhaps relevant to add that the assumption that (ii) and (iii) of the classes mentioned at the end of paragraph 14 would receive on average the same amount of medical attention as those who were on doctors' lists throughout the year seems to have been incorrect. Examination of the records for 1936 shows that if proper account were taken of these groups the number of services per insured person would be slightly reduced. Since the correction is small and to preserve the com-

parability with the earlier 1924 figures to which this correction was not applied, the correction has not been made for 1936.

Nature of Services Rendered

22 It is necessary at this stage to consider whether there has been any change in the average range of the services rendered by an insurance practitioner. In the Minister's view there has been since 1924 no such change in professional practice in regard to services that are within the scope of the general practitioner as would, without alteration of the Regulations, affect the service required under them. In so far as scientific advances have increased the armamentarium of diagnosis and treatment, the improved methods are mainly of specialist concern. In the few instances in which new methods are applied by the general practitioner (for example, the injection of varicose veins) they have tended to reduce the total work entailed. A few modern methods of treatment (for example the use of insulin in diabetes and liver extract in pernicious anaemia) have certainly prolonged life and consequently entail more extended treatment, but the incidence of these diseases in an average practice is negligible. The great bulk of the work of a general practitioner is concerned with the treatment of such conditions as influenza, catarrhal disease of the upper respiratory tract, and chronic rheumatic affections, which require the application of no greater skill in diagnosis or treatment than they did in 1924.

23 On the other hand, there are various indications suggesting that insurance practitioners have been relieved of some of the more onerous part of their work by recent developments of health services. Some interesting facts for example, emerge from the special counts made to correct the initial deductions arising from the examination of doctors' records for the years 1924 and 1936. In 1925 an examination was made of 2,000 cards relating to persons who had died since the end of 1924. The cards disclosed 36,047 services rendered during 1924 an average of 18.02 services per card. A similar examination this year of 3,685 cards relating to persons who died since the end of 1936 disclosed 36,112 services rendered during 1936 an average of 9.8 per card examined. The fall in the number of services shown per "dead" card is remarkable, particularly when the total is divided into attendances and visits.

	Attendances	Visits	Total
1924	6.8	11.2	18.02
1936	5.15	4.65	9.8

An examination of batches of "dead" cards for 1936 revealed numerous cards in which the record of treatment ended with the entry "removed to hospital" or "died in hospital" an interval of, frequently months occurring, between the last service rendered by the insurance doctor and the patient's death. In other cases it was not stated definitely on the card that the insured person died in hospital but the interval since the last service recorded (combined, in some cases with the condition from which the patient was suffering) raised the presumption that the insured person was removed to hospital about the date of the last recorded service and subsequently died there.

24 The conclusion suggested by these figures is reinforced by the fact that in recent years the number of persons admitted to the general and municipal hospitals has increased largely. Many of the general hospitals have been considerably extended since 1924 and there has been a striking growth of the various schemes such as the Hospital Saving Association and other contributory schemes etc. for securing hospital treatment where necessary in return for small weekly contributions. Moreover the Local Government Act of 1929 transferred the Poor Law infirmaries to the local authorities and freed them from the "pauper taint." These municipal hospitals have been to a large extent reorganized and improved and many of them now compare with the best voluntary

hospitals and attract an ever growing number of patients. The increase of their work is illustrated by the following figures

Voluntary Hospitals			
New In-patients		Provinces	
London			
1927	212,115	1925	528 349
1935	279 196	1935	821 865
Increase 32 per cent.		Increase 56 per cent.	
Municipal Hospitals			
In patients		Out patients	
1931	567 039		784 134
1936	729 196		1 633,522
Increase 29 per cent.		Increase 115 per cent.	

25 Similar figures, which are aggregated below, have been obtained in regard to the Edinburgh Royal Infirmary and the Royal, Victoria, and Western Infirmarys, Glasgow

In patients		Out patients	
1923	40,512	1923	151,766
1936	60,403	1936	291,204

The increase in numbers since 1923 is 50 per cent for in-patients and 92 per cent for out patients, further the hospitals estimate that of the in patients for 1936 about half were insured persons

26 From data given by approved societies under the Scottish scheme for collecting statistics of sickness among the insured population, figures relating to a sample examination of incapacities lasting over two months have been extracted, and show that the number of cases in which the incapacity was certified by a hospital official increased from 3,302 in 1934 to 3,698 in 1936, an increase of 12 per cent in two years. In the same period the number certified by insurance practitioners increased by 61 per cent and the number of insured persons by 3.8 per cent.

27 In the annual reports of the Chief Medical Officer of the Ministry of Health for 1924 and 1933 figures are given of the proportion of injuries and accidents to all cases treated in a sample of insurance practices (pp 17 and 15 of those reports). The proportion fell from 104.9 per 1,000 in 1924 to 86 per 1,000 in 1933.

28 It seems, in fact, difficult to resist the conclusion that recent developments in medicine and in public health organization have relieved the general practitioner of some of his more onerous responsibilities and it may be relevant to quote from a paper read recently to the Insurance Institute of London by Mr C E A Bedwell, House Governor of King's College Hospital, on Hospitals and Social Insurance. After referring to the development of insurance schemes such as the Civil Service Nursing Aid Association, he remarked: "All these schemes of insurance have one general effect which deserves attention. There is a marked tendency on the part of the general public to seek the services of specialists which leads the insured patient to go to the hospital rather than his panel doctor."

Proposed Extension of Medical Benefit to Juveniles

29 The Government has announced its intention of introducing legislation to provide that young persons entering insurable employment between school leaving age and the age of 16 shall be brought into insurance (for medical benefit only) immediately instead of waiting as now until they attain the age of 16 and it is estimated that this will add at the outset about one million to the number of persons entitled to medical benefit. For convenience this new class is referred to in this memorandum as "juveniles."

30 Until the general question of the capitation fee to be paid in respect of all persons entitled to medical benefit was reopened the Minister had proposed that the rate to be paid in respect of juveniles should be lower than that for the persons now entitled to medical benefit. There are however obvious administrative advantages in having one flat rate for all persons entitled to medical benefit, and

the special circumstances of this class are here set out as one of the factors to be taken into account in arriving at the capitation fee which should be paid in respect of all persons (including this new class) for whose medical treatment insurance practitioners would be responsible.

There is a strong presumption that the services which doctors would be called on to render to juveniles would be substantially less onerous than those required by the general body of insured persons. The evidence for this view may be considered under the following heads:

- The mortality rates at different ages,
- the sickness and disablement experience of insured persons at different ages,
- the return of services rendered by insurance doctors to persons under 19 years of age, and
- the absence of certification in respect of the new juvenile class.

Mortality Rates

31 The table in Appendix III, which is extracted from the Statistical Review of England and Wales, 1933 gives the annual death rates for all ages for three years 1930-2. It will be seen that at the ages of 14 and 15 the death rate is nearly at its minimum, and that for later ages it rises almost without a break. The boy or girl at that age has passed the years of maximum incidence of infectious disease and of other special risks of childhood and is as yet little affected by the chronic complaints of adult life such as chronic bronchitis, rheumatoid arthritis, cancer, etc.

Sickness Experience of Insured Persons

32 Some indication of the amount of incapacitating sickness in the new group as compared with the average amount of such sickness in the insured population generally may be obtained from a comparison of that average with the average sickness experience of the insured population nearest in age to the new group. The figures quoted are calculated from those on which the finance of the National Health Insurance Act rests (as appended for example, to the National Health Insurance (Valuation) Regulations, 1933). A valid comparison cannot be made with the experience for insured persons aged 16 to 17 because an abnormal proportion of this class will not have paid the number of weekly contributions necessary to qualify for cash benefits, and the records of benefits paid for those ages are not an adequate record of the disabling sickness. By the age of 18 this special factor may be considered largely to have disappeared, and for persons between the ages of 18 and 19 the number of weeks of sickness and disablement expected to be experienced by young men is 0.86 and for young women 1.02. For the insured population between the ages of 16 and 65 the average expected number of weeks of sickness and disablement is 1.69 for men and 2.39 for women.

In the absence of proof to the contrary it is suggested that the experience of incapacitating sickness at any age is a reasonable relative measure of the demand likely to be made for medical services by persons of that age. It should be noted also that the persons entitled to medical benefit include and the above figures of disabling sickness exclude persons over 65 years of age. The above comparison therefore underestimates the difference in demand for medical services.

Services Rendered to Insured Persons under 19

33 A special inquiry has been made into the number of services rendered during 1936 by insurance doctors to persons who first became insured during 1935 at the age of 16 or 17 and were still on the doctors' lists at December 31, 1936 by which date they would be under 19 years of age. A special difficulty is encountered in considering the services rendered by doctors to this class of insured person. As is well known many insured persons do not trouble to place their names on a doctor's list until they

need medical attention, and this period may even extend to several years. During this period the insured person is unallocated. In all there are nearly 500,000 unallocated persons in England and Wales out of the total insured population of roughly 16,000,000. A large part of this 500,000 consists of young persons under 20 years of age. By the time a person has been in insurance for several years he has almost invariably had need of medical attention and has taken steps to select a doctor. The young persons under 19 years of age on doctors' lists are therefore only a selected portion of the total insured population of that age, and are largely those who have needed treatment in the comparatively short period since they entered into insurance. A survey of services rendered to persons of this age thus includes those who have received treatment since entry into insurance but excludes many who have not required medical attention; the average number of services to such persons per insured person on list under 19 years of age shown by the survey is therefore an abnormally high figure.

34 The result of the special survey is as follows.

Of the 600 practices included in the main survey fifty-nine practices were examined for persons under 19, the practices being specially selected so that the collective average number of services rendered by the fifty-nine doctors to their insured patients was nearly equal to the collective average of the 600 practices. The lists of the fifty-nine doctors included 2,883 persons under 19 years of age who entered insurance in 1935.

The services rendered to them were as follows.

	Number	Average Number per Card examined
Attendances	6,745	2.34
Visits	1,342	0.47
Total services	8,087	2.81

Even these figures, which as explained above, exaggerate the average number of services for insured persons of that age, indicate that persons under 19 receive on average substantially fewer services than are rendered to insured persons generally, and that in particular the number of visits which the doctor is called upon to make is low. It may reasonably be presumed that the new class of juveniles will receive broadly the same amount of medical attention as young persons now in insurance under the age of 19.

Absence of Certification

35 As indicated above, the juvenile class will not be entitled to sickness or disablement benefit until they attain the age of 16 (and have paid the qualifying number of contributions after reaching that age), and there will be no obligation on the insurance doctor to furnish certificates of incapacity. The responsibilities of an insurance doctor in connexion with certification include not only the giving of certificates but also the obligation to furnish to the Regional Medical Officer any information which the latter may require with regard to any patient to whom the practitioner has issued or declined to issue a certificate of incapacity.

36 Not only does the obligation to give certificates involve the doctor in extra clerical work (the value of which in terms of capitation fee has been estimated at 6d.) but in

the Department's experience an insured person who is entitled to certificates of incapacity makes visits to his doctor in connexion therewith which otherwise he would not make, if only because an insured person who has recovered from illness must go to his doctor to obtain a final certificate. There is a tendency also for a patient who has seen his doctor say on Tuesday to pay a further visit on Thursday to get his weekly certificate, when otherwise he would probably have waited until the Saturday before going to the doctor again. All the persons under 19 years of age included in this special survey would normally be entitled to sickness benefit, but not generally to disablement benefit. The new juvenile class will be entitled to neither sickness nor disablement benefit.

37 There is good cause, therefore, to presume that the new juvenile class will in fact receive still fewer services than insured persons under 19. Bearing in mind that the average number of services for those under 19 (2.81) is itself an inflated figure (paragraph 33), it appears reasonable to assume that the average number of services rendered to the new juvenile class will not be materially in excess of one-half the average number of services rendered to the insured population generally and will include a relatively small proportion of visits.

38 Reviewing all the available evidence and having regard to the number and nature of the services likely to be rendered and the absence of certification, it appears not unreasonable to assess the claim which juveniles will make on the doctors' time and energies as roughly one-half that made by an equivalent number of adult insured persons.

As the total number of insured persons in Great Britain is in the neighbourhood of 18,000,000, the inclusion of a further 1,000,000 at one-half the rate of services would warrant the reduction of the capitation fee by about 3d. for the whole insured population. Alternatively, if this number were included at two-thirds the rate of services the equivalent reduction would be about 2d.

Summary

39 The results of the survey made above of the changes which have occurred since 1924 and of the effect of the proposed introduction of the juvenile class, may be summarized as follows.

Change in Capitation Rate due to	Increase	Decrease
	d.	s. d.
Increase in the average number of services rendered by insurance doctors	4	—
Fall in cost of living	—	0 5
Fall in expenses of practice	—	0 7
Reduced services to juveniles	—	0 3
	4	1 3

yielding on balance, a reduction of 11d., or, on the alternative mentioned at the end of paragraph 38, a reduction of 10d.

This reduction however, takes account only of those data which can be evaluated and disregards such qualitative factors as are indicated by the increasing reference of patients to hospitals. The Minister therefore submits that the appropriate fee payable to insurance doctors as from January 1, 1938, for the treatment of insured persons, including persons under the age of 16 years proposed to be brought into national health insurance, is 8s.

APPENDIX I

CORRESPONDENCE BETWEEN MINISTER OF HEALTH
AND INSURANCE ACTS COMMITTEEMINISTRY OF HEALTH
WHITEHALL, S.W. 1

December 23 1936

Sir,

I am directed by the Minister of Health to refer to the recent conference held between representatives of the Insurance Acts Committee and officers of the Department on the question of the capitation fee to be paid to insurance practitioners in respect of employed juveniles under the age of 16 who would be brought within the National Health Insurance scheme under the legislation proposed to be introduced by the Government.

The Minister has given careful consideration to the representations made on behalf of the Insurance Acts Committee. While he remains satisfied that persons within the age group in question are likely, having regard to their comparatively low sickness experience to make fewer demands on the services of practitioners than persons of older ages he does not wish to press this point unduly, since he recognizes that in the interests of public health it is desirable that juvenile workers should remain as far as possible under medical supervision.

On the other hand the Minister considers that in suggesting that on account of the absence of any obligation to issue certificates of incapacity the capitation fee should be only 5 per cent. less than that paid in respect of adults the Insurance Acts Committee have attached far less weight to this factor than the circumstances require. It seems clear to him that account must be taken not only of the medical and clerical work involved in the actual issue of certificates but also of the fact that patients who are not entitled to weekly payments of sickness benefit will not present themselves to their doctors with such frequency as those who are so entitled, and therefore require the certificates in support of their claims. The Minister cannot accept the contention that in view of requests for certificates required by the patients' employers practitioners would not in effect be relieved of this work to any considerable extent.

In all the circumstances the Minister is prepared to provide for a capitation fee of seven shillings and sixpence on the understanding that if the standard capitation fee for adults should be increased or reduced in future the rate for juveniles should be varied proportionately.

The Minister also wishes to take this opportunity of informing you that he has found that the number of new patients who would be brought within the scope of medical benefit in Great Britain is owing to the recent increase in the employment of juveniles likely to be about 1 000 000 at the outset instead of 700 000 as intimated to the representatives of your Association. It will be appreciated however that the number is subject to variation for reasons dependent on the birth rate and that in any case it will fall when the change in the school leaving age comes into force.

I am to add that the Minister has consulted the Secretary of State for Scotland and the Ministry of Labour for Northern Ireland and that they wish to be associated with him in the terms of this letter.

I am Sir your obedient Servant

E. J. MAUDE.

THE MEDICAL SECRETARY
BRITISH MEDICAL ASSOCIATIONBRITISH MEDICAL ASSOCIATION HOUSE
TAVISTOCK SQUARE
LONDON W.C. 1

January 8 1937

Dear Sir,

I refer to your letter of December 23 conveying the offer of the Ministry of Health of a capitation fee of 7s. 6d. for medical attendance for employed juveniles under the age of 16 who would be brought within the National Health Insurance scheme under the legislation proposed to be introduced by the Government.

At a Special Conference of Representatives of Local Medical and Panel Committees held yesterday the following resolutions were passed unanimously:

That the offer of the Ministry of Health of a capitation fee of 7s. 6d. for medical attendance on insured persons under 16 years of age be rejected.

That this Conference recommends insurance practitioners to decline service for the provision of medical benefit for insured workers under 16 years of age at the terms offered by the Minister of Health.

That in view of the inadequacy of the existing capitation fee and pending the result of negotiations for its increase this Conference is not prepared to accept for attendance on insured workers under 16 years of age a capitation fee less than that which is paid for adult insured workers.

That the Insurance Acts Committee be authorized to take action in the light of the decisions reached by the Conference.

Yours faithfully,

CHARLES HILL,
Deputy Medical Secretary British
Medical AssociationTHE SECRETARY
MINISTRY OF HEALTHBRITISH MEDICAL ASSOCIATION HOUSE
TAVISTOCK SQUARE
LONDON W.C. 1

February 11 1937

Dear Sir,

I am instructed by the Insurance Acts Committee to make formal application on behalf of the medical practitioners engaged in National Health Insurance medical practice for an increase in the annual capitation fee this increased capitation fee to be applicable to all insured persons including those under 16 shortly to be brought into National Health Insurance as a result of legislation promised by the Government.

It will be recalled that the capitation fee of 9s. has remained unchanged since it was assessed by the Court of Inquiry in 1924. Since that year as a result of the operation of a number of factors insurance practitioners have borne an increasing responsibility in respect of insured persons and it is considered that the time is appropriate for a substantial increase in their remuneration.

At the Annual Conference of Representatives of Local Medical and Panel Committees in 1936 the following resolution was passed:

That the Insurance Acts Committee be instructed to proceed with an application to the Minister of Health for an increase in the capitation fee.

I am to ask that the Minister will be good enough to receive a deputation from the Insurance Acts Committee in order that the case may be placed before him.

Yours faithfully,

CHARLES HILL,
Deputy Medical SecretaryTHE SECRETARY
MINISTRY OF HEALTHMINISTRY OF HEALTH
WHITEHALL S.W. 1

March 22 1937

Sir,

I am directed by the Minister of Health to refer to the deputation from your Committee which was received on 11th instant and to state that the Minister has been considering in conjunction with the Department of Health for Scotland the terms of reference to the proposed Court of Inquiry. The terms of reference which are considered appropriate in the present circumstances are shown in the enclosed draft. It will be seen that the form of words follows that used in the case of the Court of Inquiry in 1924 subject to such modifications as are necessary to cover the projected inclusion of juvenile employed persons in the National Health Insurance scheme so far as medical benefit is concerned.

The Minister is not yet in a position to inform you of the names of the proposed members of the Court of Inquiry but it is contemplated that the Court will consist of three members as in 1924 and that the procedure generally will be on the same lines as on that occasion.

A further communication on these matters will be addressed to you as soon as possible.

I am Sir Your obedient Servant

A. W. NEVILLE

THE SECRETARY
INSURANCE ACTS COMMITTEE
BRITISH MEDICAL ASSOCIATION

APPENDIX II

INSTRUCTIONS FOR EXAMINATION OF DOCTORS
RECORDS

(A)

TO DIVISIONAL MEDICAL OFFICERS

SPECIAL INSPECTION OF RECORDS

I informed you at our Conference on January 28 that as the amount of the Capitation Fee payable to insurance practitioners for insured persons on their lists is at present under review the R M staff might be required to undertake a special scrutiny of medical records for the purpose of ascertaining approximately the number of services given by insurance practitioners during the year 1936. It has now been decided to proceed with the least possible delay and the matter should therefore be regarded throughout as urgent.

The inspection will be conducted on similar lines to those followed at the previous inspection in the early months of 1935. The records of twenty practices will be inspected in each region and for each division as a whole the three types of practice (urban mixed and rural) should be represented approximately in the proportions of 7 2 1.

We agreed at the Conference that the method which was most likely to indicate whether there had been any change in the number of services rendered by practitioners would be to scrutinize the records of the same practices which were used for the previous Special Inspection in 1935 provided that the R M O had no reason to believe that the record keeping in any of these practices had in the meantime deteriorated. I enclose a list of the names and addresses of the practitioners in your division whose records were scrutinized on that occasion. From this you will be able to prepare a list of those practitioners whose records were scrutinized in each region. The appropriate list should be forwarded to each R M O, who should be instructed to inform the D M O whether he has any reason to think that any of the practices mentioned in the list will not be suitable for scrutiny on this occasion and to submit the names of thirty practitioners (a partnership counting as one) including those practitioners on the list supplied whom he thinks there is no reason to exclude who have not fewer than 500 persons on their list and who are known from the R M O's personal experience or from the personal files to keep reasonably accurate records. The type of each practice will be indicated by the R M O in the list submitted.

The R M O should as far as the circumstances of his region allow include in his selection the three types of practice in the proportions already indicated. Where an R M O finds difficulty in making his selection from good records in these proportions he will complete the required total number of practices by increasing the proportion of the available type or types.

In view of the urgency it is hoped it will be found possible to secure that the lists prepared by the R M Os are submitted to the D M Os as soon as possible and not later than February 22.

When the R M Os lists have been received D M Os bearing in mind that as many as possible of the practices in which the records were scrutinized at the previous Special Inspection are to be included will proceed to make a final selection to secure that the total number of practices chosen in the division as a whole is twenty multiplied by the number of regions and that urban mixed and rural practices are included approximately in the proportions of 7 2 1.

An R M S Minute of Instruction to the staff and a further D M O Minute will be issued shortly. Until these have been issued it is of importance that no practitioner should be approached in the matter or informed that such an investigation is contemplated.

R PATERSON

February 11 1937

(B)

TO DIVISIONAL MEDICAL OFFICERS

THE SPECIAL INSPECTION OF MEDICAL RECORDS

A final decision in regard to the Special Record Inspection of which you were informed in D M O Minute 4 37 has only now been taken and at the same time the matter has become urgent.

An R M S Minute of which a typed copy is attached has been sent to-day to New York and it is hoped it will be ready for use to-morrow or at latest on Friday when it will be dispatched direct to the R M staff. The special schedules and

summary forms are being printed but will not be available until Monday, when supplies will also be dispatched direct to R M offices.

From the R M S Minute it will be noted that R M Os will look to their D M O for instructions regarding the time to be devoted by themselves and by the D R M Os respectively to this work. This time is to be taken by Divisional Medical Officers as the maximum possible having regard to the avoidance of material delay in the clearance of references, and during the course of the investigation the services of Part time Referees should be employed to the utmost limit.

It is hoped that in all divisions the D M O will by this time have received from his R M Os the list of thirty practices and he should at once proceed to select the requisite twenty practices in each region and send the selected list to the R M O. The programmes of both R M Os and D R M Os should be arranged to enable the officers to commence the actual inspection of records on Thursday February 25. This means that notification of the practitioners concerned will have to commence on Monday or Tuesday next and in transmitting the list of selected practices D M Os will so inform their staff.

It is hoped that the whole of the actual work of inspection will be completed not later than March 9 but as the Minister is meanwhile extremely anxious to have even an approximate guide to the position as soon as possible I have instructed the staff to forward the schedules for each practice as soon as completed direct to me.

R PATERSON

February 17 1937

(C)

TO REGIONAL MEDICAL STAFF

SPECIAL INSPECTION OF MEDICAL RECORDS

1 The R M staff have already been informed through their D M O that it will be necessary to examine medical records relating to the year 1936 in order to extract such particulars as will enable an estimate to be made of the amount of medical attendance given by insurance practitioners in that year under the Medical Benefit Regulations. The matter has now become urgent, and both R M Os and D R M Os will devote to the work the whole of the time which the D M O decides is not required for reference or routine office work.

2 Each R M O will receive from his D M O a list of the practices in his region the records of which are to be examined and he will be informed of the times to be allotted to the work by the R M O and D R M O respectively. R M Os will apportion the work of inspection between themselves and the D R M Os in such a manner as will secure the earliest completion of the task and D R M Os will in this matter act under the direct instruction of their R M O.

3 For notifying the practitioner of the proposed visit Form R M 51b will not be used but a personal note will be sent indicating the special statistical nature of the investigation.

4 From the records of each practice 500 cards (subject to what is stated in paragraph 8) will be selected in the manner described below. Care must be taken that any batches of cards kept apart from the general stock—for example cards of the persons at the time under treatment—are included among the cards examined. Care will also be necessary to deal with the particulars of continuation cards inside envelopes even where there is no entry on the envelope itself.

5 In order to avoid the introduction of unnecessary assumptions in the deductions to be drawn from the figures obtained examination particulars should be taken from those cards only which were in the doctor's possession throughout the year 1936. These cards should be identified by the fact that the latest date stamped by the Committee in the space headed Committee's cipher and date is earlier than January 1 1936.

6 It is important that no entries relating to any year other than 1936 should be included and if on any card it is uncertain whether any entries relate to 1936 or not the card should be rejected. If the proportion of such cards in any practice is large the practice should not be included among those reported on but another should be substituted.

7 The scrutiny will begin with the cards of persons whose surnames start with the letter A and will be continued with the cards under succeeding letters in alphabetical order (the cards always being rejected which are shown by the date stamp to have been received by the doctor in 1936 or later) until the particulars have been extracted from the required number of cards.

8 It will in general be impracticable to sort together in an alphabetic order the total number of cards when they are normally kept by the doctor in two or more batches. In such

cases accordingly the "A" cards should be examined in the several batches care being taken that all the batches have been examined before the examination of the "B" cards is begun, later letters will be dealt with similarly and the examination continued until at the end of a letter or a combination of letters (for example Da De etc.) an aggregate which approximates as nearly as may be to 500 cards has been reached.

9 Special schedules or working sheets for the entry of the required particulars are being prepared and a supply will be forwarded to each R.M.O. within the next few days. At the head of the first schedule will be entered the name and address of the practitioner or firm of practitioners and the total number of insured persons on this list and the character of the practice will be indicated by classifying it as Urban (U) Mixed (M) or Rural (R). At the head of the second and subsequent schedules the doctor's name alone need be entered. The schedules relating to each practice should be consecutively numbered at the top right hand corner of the schedule.

10 On the schedule a line is to be used for the entry of particulars of each card examined the entries being in the first column the number of attendances and in the second column the number of visits. The schedule is a reprint of that used in former similar investigations and contains a third column which was then used for the entry of certificates. On the present occasion statistics relating to certificates are not required and this third column will be ignored. When there was no attendance or no visit in the year a dash will be made in the appropriate space on the line.

11 It will be noted that the schedule contains separate columns for entries relating to male and female patients respectively. It is important that separate figures should be obtained for each sex.

12 In addition to the schedules each R.M.O. will receive a supply of forms of summary. One of these will be completed in respect of each practice by the R.M. clerk as soon as possible after the inspection and the schedules together with the summary will at once be transmitted to the S.M.O. direct.

R PATERSON

February 18 1937

APPENDIX III

TABLE XXX

STATISTICAL REVIEW OF ENGLAND AND WALES

Annual Death Rates per 1000 Living at each Year of Age in the Three Years 1930-32

Age	Males	Females	Age	Males	Females	Age	Males	Females
All ages	12.7	11.2	33	3.8	3.4	67	46.4	33.8

BRITISH MEDICAL ASSOCIATION'S REJOINDER

Basis of Determining Remuneration of Insurance Practitioners

(Paragraphs 1-3)

1 The Insurance Acts Committee does not dispute the general statement of the factors to be considered by the Court of Inquiry with one important qualification. The Court of Inquiry of 1924 considered certain evidence, including a quantitative estimate of work undertaken by insurance practitioners relating to and collected in not the year 1924 but a previous year. It is the changes if any which have taken place in certain factors as expressed in the difference between the evidence before the Court in 1924 and the evidence before the Court of 1937 that are under consideration.

2 The Ministry would have given a truer comparison between 1924 and 1936 if it had added to its statements that the number of insured persons had increased by 18 per cent and the number of insurance practitioners by 28 per cent the further statement that in that time the number of doctors on the *Medical Register* in Great Britain had in that period increased by 22 per cent. After allowing for the disproportionate growth of other fields of medical practice there is no evidence for any suggestion that the increase in the number of insurance doctors indicates a more attractive service.

3 Now that National Health Insurance is an established part of the nation's health services no general practitioner who is not practising exclusively among the middle or upper classes can afford to remain outside it. Since 1924 the average number of insured persons on a doctor's list has fallen from 976 to 916 and the average remuneration from £2.50 to £2.13.

Fall in the Cost of Living

(Paragraphs 4-9)

4 The Committee accepts the conclusions of the Ministry in regard to the cost of living.

Fall in the Expenses of a Doctor's Practice

(Paragraphs 10-13)

5 This Section of the Ministry's memorandum opens with the statement that the Ministry has not detailed information as to the proportion of a doctor's gross income that is absorbed by practice expenses or the exact proportion of these expenses that is due to the cost of locomotion. This deficiency can now be remedied by the Insurance Acts Committee.

6 The Ministry makes two main assumptions

(a) that in 1924 practice expenses constituted 25 per cent of the gross income

(b) that in 1924 the cost of locomotion amounted to 75 per cent of all practice expenses

(a) PRACTICE EXPENSES

7 The summarized accounts of a number of doctors for two periods of three years 1923-5 and 1929-31 are now available. Formerly the only information on this subject was that obtainable from a comparatively small number of practices collected during the abnormal years of the war. In order that the fullest information might be available the Insurance Acts Committee arranged for the figures of a number of widely distributed practices to be furnished for two periods of three years. These

returns which will be available to the Court, are summarized in the following table

Year	Type of Practice	No of Practices	No of Practitioners	Average Income per Practitioner	Average Income per Practitioner	Percentage of Practice Expenses to Income	Percentage of Expenses to Income of all Practices Combined
1923	1	28	30	£ 1,493	£ 1,393	37.67	33.66
	2	66	93	2,363	1,677	32.73	
	3	29	46	2,788	1,757	34.03	
	4	5	6	2,013	1,667	28.10	
1924	1	30	32	1,472	1,380	36.79	34.61
	2	71	102	2,457	1,710	34.45	
	3	30	47	2,742	1,750	34.88	
	4	5	6	1,900	1,583	24.94	
1925	1	31	32	1,444	1,399	36.92	33.91
	2	71	103	2,479	1,709	34.02	
	3	29	45	2,830	1,824	32.90	
	4	5	6	2,005	1,671	26.8	
1929	1	31	34	1,621	1,475	35.33	34.03
	2	71	109	2,515	1,638	32.37	
	3	30	46	3,095	2,018	36.90	
	4	5	6	1,988	1,645	30.50	
1930	1	32	35	1,588	1,452	36.36	34.16
	2	72	110	2,541	1,645	33.70	
	3	30	46	3,061	1,996	37.70	
	4	5	6	2,138	1,932	32.31	
1931	1	32	35	1,592	1,456	36.44	34.77
	2	70	108	2,512	1,629	33.15	
	3	30	46	3,058	1,994	37.70	
	4	5	6	2,083	1,736	28.03	

Percentage of Total Expenses to Income for Each Type of Practice

Type of Practice	Period	Percentage of Total Practice Expenses to Income
1 Insurance with dispensing for all patients	1923-25	37.11
	1929-31	36.04
2 Insurance with dispensing for private patients only	1923-25	33.77
	1929-31	33.08
3 Insurance with dispensing for part insured and all private patients	1923-25	33.95
	1929-31	37.43
4 Insurance with no dispensing	1923-25	26.63
	1929-31	30.29

8 The class of practice in respect of which the ratio of 25 per cent (total expenses to gross receipts) was adopted in 1924 is that referred to as Type 2. It is shown that a more accurate figure for this ratio is 33 per cent, an increase of expenses, in terms of the 9s capitation fee, of approximately 9d.

9 Whatever reduction in travelling costs can be shown to have taken place or whatever is the proportion of expenses which goes in locomotion costs, the gross practice expenses can be shown to be substantially higher than those accepted in 1924.

(b) LOCOMOTION

10 The assumption that the cost of locomotion was 75 per cent of total practice expenses is disposed of by these accounts. Travelling costs in terms of percentages of gross income and percentages of gross practice expenses for each of the four groups are as follows:

Type of Practice	Period	Percentage of Travelling Expenses to Income	Percentage of Total Practice Expenses to Income
1 Insurance with dispensing for all patients	1923-25	11.57	37.11
	1929-31	12.06	36.04
2 Insurance with dispensing for private patients only	1923-25	10.56	33.77
	1929-31	10.62	33.08
3 Insurance with dispensing for part insured and all private patients	1923-25	13.27	33.95
	1929-31	11.28	37.43
4 Insurance with no dispensing	1923-25	11.73	26.63
	1929-31	14.52	30.29

The Treasury Figures

(Paragraph 11)

11 Figures which represent the amounts per mile which another Government department sees fit to pay at different times appear to have no relevance to the issue unless they are accompanied by the detailed calculations upon which they are based. Such figures may well be an example of the Treasury's generosity in 1924 or its parsimony in 1937 or both.

12 The Treasury figures do not agree with those put forward by the Ministry itself based on its own calculations.

a fact which demonstrates that either the Treasury figures or the Ministry's figures (or both) are inaccurate. The figures put forward by the Association in its first memorandum to the Court of Inquiry were supplied by the Automobile Association, a body independent of the Ministry, the Treasury, and the Insurance Acts Committee.

13 In any case the statement that the conditions under which civil servants use their cars do not appear to differ from those of travelling done in the course of an insurance practice sufficiently to invalidate the comparison is unsupported by arguments that civil servants using their own cars on public business make a large number of short journeys, with repeated stopping and starting or that they need to maintain a car of the type and in the condition necessary for medical practice.

14 It is significant that these Treasury rates, ostensibly put in for comparative purposes, to show the reduction in rates between 1924 and 1937, are in paragraph 13 used as if the rates themselves had been established. The Ministry having argued from its own figures that the reduction in motoring costs is 27 per cent proceeds with the aid of the Treasury figure and an irrelevant hireage figure, to make it 35 per cent.

The Ministry's Calculations

(Paragraph 12)

15 The Ministry quotes from *The Motor Industry of Great Britain* published by the Society of Motor Manufacturers and Traders, as showing a reduction in the price of private cars of 50 per cent between 1924 and 1935.

16 The index figures for 1924 and 1935 given in this publication relate to the cost measured in horse power units of the cars purchased in the greatest numbers by the motoring public. In 1935, of all cars purchased almost 30 per cent were of horse-power 8 or under, and almost 61 per cent were of horse power 10 or under. In 1927, the earliest year for which figures are given, of all cars purchased just over 16 per cent were of horse power 8 or under and 23.5 per cent were of horse power 10 or under.

17 Have insurance practitioners been able to enjoy this average reduction in cost by utilizing lower power cars in the same proportion as the general motoring public? They have not, for the nature of the travelling required of them has necessitated the use of cars of fairly high horse power and at least medium size. In consequence their purchase costs have not fallen by 50 per cent.

18 A very important consideration is entirely neglected by the Ministry. It is assumed in its calculations not only that insurance practitioners utilize 10 horse power cars but also that they keep them in use for five years. It is difficult to conceive of an assumption more removed from reality. The practice of changing cars every one two or three years is in the medical profession practically universal. It renders nugatory calculations based on the five years' use of a 10 horse-power car. Those few doctors who do use 10 horse power cars usually replace them after a year's use or at the most two years' use. Of those who use cars of horse power 12-20, the great majority usually replace them after one two or three years. The net effect of this practice is that the factor of depreciation is the one of greatest importance.

19 On receiving the Ministry's memorandum the Insurance Acts Committee decided to ask the Society of Motor Manufacturers and Traders to name an independent motoring expert. Mr Scott Hall was one of two persons named and he was asked to prepare an independent statement on the changes which have taken place since 1924 in the motoring costs of general practitioners. Mr Scott Hall is a member of the Institute of Automobile Engineers and a member of the Industrial Transport Association. He is an acknowledged expert on the subject of transport.

economics and consultant on this matter to *The Commercial Motor*. His report is given in full below

5 Tudor Chambers
Station Road
London N.22.
May 17, 1937

To the Medical Secretary
BRITISH MEDICAL ASSOCIATION
19b Tavistock Square
London WC1

SIR

I have pleasure in presenting in accordance with your request figures for the operating costs of motor cars as used by general practitioners. The figures appear in the Schedule and give data for cars operated during the year 1924 and also for cars in use at the present time. The following notes are explanatory of the items and of the way in which I have arrived at the figures

Initial Outlay on Car

In arriving at this I have in the first place taken the list prices of twenty two cars of horse powers ranging from 12 to 17 and prices from £210 to £465. All of them are of the type normally used to a greater or less extent, by doctors. In arriving at the average price however I have taken cognizance of the fact that certain particular makes and types of car are more popular for this purpose than others and have weighted the averages accordingly.

By the foregoing method I have arrived at the figure of £320 as being the average price of a doctor's car in 1924 and £255 the corresponding figure to-day.

In the course of making this analysis I came to the conclusion that the average horse power in 1924 was a very small fraction in excess of 12 and for the present day 12.8. The difference is one which might naturally be expected as the result of the diminution in the annual Road Fund tax from £1 per horse power to 15s per horse power.

My attention has been drawn in this particular aspect of the matter to certain figures produced by the Society of Motor Manufacturers and Traders which appear to show that the average price of motor cars has halved in the period under review. In my opinion the calculations which form the basis of that conclusion have no bearing whatever upon the present investigation.

In 1924 there was a considerable number of motor cars of a luxury type and of a price which would not be considered as practicable in the case of a purchase of a car by a doctor. None of those cars has been taken into consideration in the investigations which form the subject of this present report.

Road Fund Tax

Thus as quoted in the Schedule is on the basis of £1 per horse power for a 12 h.p. car in 1924 and 15s per horse power for a 12.8 horse power car in 1937.

Insurance

The cost of insurance on the whole is somewhat greater now than it was in 1924. It is true that there is a slight reduction in what might be termed basic premiums but this is more than offset by the considerable increases in those premiums as applied to cars in use in the Metropolitan Police area and in what are called the black areas. The figures quoted for insurance premiums in the two columns in the Schedule are as near as can be assessed fair averages for the periods named.

Interest

In calculating the figures for interest on first cost I have taken 5 per cent per annum for 1924 and 3½ per cent per annum for 1937.

Car Hire

It is somewhat difficult to assess the extent to which the expense of putting a car has diminished but taking provincial as well as metropolitan areas it is reasonable to assume that an average of 5s 6d per week would apply in 1924 and 5s per week at the present time. In assessing the figure at this amount I have in mind the fact that a considerable proportion of doctors house their cars on their own premises in which cases the assessment of rent and rates would be lower than the figure named. That offsets a debit on the balance in excess of the average which is involved when a car has to be parked elsewhere.

Depreciation

The figures for depreciation are not calculated and are not on any hypothetical basis whatever. Actual selling prices of cars have been taken after periods of use of one, two and three years. The average has then been taken of these figures, subject to the following assumptions.

- That only a minority of doctors change their cars annually.
- That a considerable number do effect such a change in alternate years—that is to say, they keep a car two years and then dispose of it in part exchange for a new one.
- That a fair number of doctors keep their cars for three years before disposing of them.
- That a minority keep them for more than three years.

In calculating the average figure no cognizance has been taken of cars kept for more than three years. It is certain that in such cases the additional cost of maintenance and repair involved in the third and subsequent years will be more than enough to compensate for any apparent saving in respect of depreciation. (See also notes on item 'Maintenance'.) The figure included on account of depreciation is a fair average, subject to the above hypotheses. A doctor who changes his car annually will be at a slightly greater expense on account of this item. A doctor who keeps his car three years may save a few pounds. The figure as it stands is representative.

Maintenance

The cost of maintenance as set down is calculated on the assumption that a car is not kept for more than three years. It provides for the vehicle being thoroughly washed and polished on an average not less frequently than three times in two weeks for periodic greasing and lubrication and minor adjustments for decarbonizing once a year and for such small and inexpensive replacements as are all that should normally be required in the period named having in mind the mileage which is expected to be covered annually.

The foregoing are fixed or standing charges, and the total of them is not likely to be materially affected so long as the annual mileage does not greatly differ from that which has been suggested to me.

Petrol Consumption

The petrol consumption of motor cars of equivalent power has not improved to any appreciable extent as between 1924 and the present day. The very slight diminution which might have been recorded is offset by the increase in the average horse power of cars used for the purpose in view.

The figure of 20 miles per gallon meets the case in respect of both periods. During 1924 there were two alterations in the price of petrol which varied from 1s 11d to 1s 6½d. 1s 9d per gallon is a fair average price and that is what has been taken to calculate the figures for 1924. For 1937 the current price of 1s 7½d per gallon is taken.

Oil Consumption

In assessing the figures for expenditure on lubricating oil provision has been made for periodic replenishment of the crankcase as well as for the occasional and customary addition to that which is already in the sump.

Tyres

Recent increases in the price of tyres have brought the cost of equipment for the average doctor's car to about the same total to-day as existed in 1924. The price of a set averages £18 4s. In 1924 the life of a set of tyres under such conditions for use as are involved in the operation of a doctor's car was 10,000 miles. To-day the corresponding life is 14,000 miles. In making this statement I should draw attention to the fact that during the last three or four years there has for various causes been a diminution in the wear or mileage to be expected from car tyres.

Totals

The sum of the above running costs has been multiplied by 8,000 the annual mileage to give a total of running cost, this added to the total of fixed charges is the total cost per annum. For 1924 that cost was £209 3s 4d as against £197 12s to-day.

An Increase Probable

In conclusion I would draw attention to the final note on the Schedule in which provision is made for an increase of 5 per cent on the current figures as set down in that Schedule. In my opinion it should be appreciated by all parties concerned that the prices of all commodities involved in the

sheet" from which the final calculations are made which produce the final figures.

Summary

35 To summarize the position

I The Ministry's method of collecting data of items rendered is imperfect

II The Ministry's returns are inevitably incomplete because in practice all items are not recorded on the medical record cards

III If in the Ministry's returns the proportionate increase in number of persons attended is compared with the proportionate increase in items of service the imperfection is obvious

IV A comparison of the Ministry's return for frequency of prescribing and the Ministry's return for total items of service rendered can be explained only on the assumption that the Ministry's returns for items of service are incomplete

V Even in its own calculations the Ministry makes a false comparison, and returns as approximately 5, a percentage which should be between 9 and 10

VI The returns submitted by the Insurance Acts Committee are both exhaustive and reliable, relating to a far greater number of insured persons for a much longer period and collected by a method which is free from the defects in the Ministry's method

VII A comparison between the figures (375 items) placed before the 1924 Court and those (approximately 5 items) now available justifies a claim for an increase on the 9s capitation fee of 3s. After weighting on the lines suggested by the Ministry the percentage increase in work becomes 36 per cent, justifying an increase in the capitation fee of 3s. 3d

Nature of Services Rendered

(Paragraph 22-28)

36 It is not easy to see the relevance of much that appears in this section, the main conclusion to be drawn from it is that its authors are without present or recent experience of the realities of general practice. The Ministry contends that amid the rapid and extensive changes which have characterized medicine in the last thirteen years insurance practice has stood still, and that if there has been anything new it has merely lightened the responsibility of a group of practitioners whose attention is focused on influenza, catarrhal disease, and chronic rheumatism. These statements are made in relation to a service which, in his report for 1935, the Chief Medical Officer described as 'one of the most effective branches of the public health service. In the same report he said

The vast majority of insurance practitioners interpret the terms of their contract in no niggardly spirit, and undoubtedly the standard of the service they give is not only high but is yearly rising as fresh advances of medical science add to the general practitioners' armamentarium in diagnosis and treatment

Which statement is right—the one made in 1935 or the one made in 1937? Is the Ministry ignorant of the greatly improved methods in the diagnosis and treatment of a large number of physical and psychological conditions some of which are referred to in paragraphs 6-8 of the Committee's memorandum? Does it not value the newer attitude of medicine in its emphasis on positive health and preventive medicine? Is the correction of a minor departure from health before it becomes a major one of less value to the State or does it involve less responsibility on the part of the practitioner than the treatment of grave conditions within the walls of a hospital?

37 The choice of catarrhal conditions and chronic rheumatism as conditions in which no greater skill in

diagnosis and treatment is required is unfortunate, as they are good examples of conditions in which advances have been made

38 The question of the number of items of service has been dealt with elsewhere, although some of the references in these paragraphs appear to have relevance to this issue. It is common knowledge that as the result of advances in medicine and surgery, the hospital can now do much more for a greater number of persons than formerly. But what is the relevance of this? Specialist or consultative work such as is undertaken at hospital is not within the insurance practitioner's contract. Because more specialist work is done it does not follow that the responsibility of the insurance practitioner is lightened or that his work is less onerous. It is he who sends the patients to hospital and the increased usefulness of the hospital imposes upon him the heavier responsibility of deciding in which cases specialist advice or treatment is necessary. The responsibility of diagnosing a case of appendicitis at home and sending the patient to hospital is no less than that of operating in the hospital. And the fact that a life in this condition can be saved by operation confers upon practitioners the increased responsibility in all cases of lower abdominal pain, whether they turn out to be appendicular in origin or not. In short, the greater the number of conditions in which hospital advice or treatment is necessary the heavier the responsibility of the doctor who diagnoses them and sends the patients suffering from them to hospital.

39 Similar considerations apply to out-patient departments. The British Medical Association has long urged and with considerable success that, except in emergency, out-patient departments should be utilized for consultation purposes only. To-day few hospitals admit patients to their out-patient departments who attend without a doctor's letter; they are consultative in character. This change is referred to in the report of the King Edward's Hospital Fund for London for 1935.

The fluctuations in the figures in the tables may be an indication that the number of new out-patients is approaching a fairly constant level, one reason for this may be the change that is taking place in the work of the out-patient department in the direction of developing its consultative functions and of providing facilities for specialized long treatments while discouraging trivial complaints that do not require hospital treatment or for which other more suitable agencies are available.

40 In view of these considerations the actual numbers and percentages relating to hospital in-patients and out-patients are immaterial. But they provide a further illustration of the Ministry's use of statistics. The in-patient figures for London and the provinces are given, but not the figures for new out-patients despite the fact that they are easily collated from the *Hospital Year Book* and the report of the King Edward's Hospital Fund for London. They show an increase of out-patients between 1927 and 1935 of 18 per cent. The only out-patient figure the Ministry gives, that for municipal hospitals, is grossly misleading. There were few if any out-patients at municipal or county hospitals before 1930. The development of out-patient departments at municipal hospitals followed the Local Government Act, 1929 which came into operation in 1930 and has only in the last three years been substantially implemented. The Ministry by comparing the years 1929 and 1936 could have shown a percentage increase running into millions—a figure of as much value as the one given.

41 The fact that persons suffering from injuries resulting from accidents are treated in greater numbers than formerly at hospital where the all important x-rays can be utilized does not seem to indicate that the items of service undertaken by insurance practitioners are less onerous or less responsible.

42 Underlying this section is the assumption that the more serious conditions from which persons suffer—the more dramatic they appear to the public mind—the

greater responsibility and skill involved. To a great extent the contrary is the case. The general practitioner provides to-day a service which, whether in its preventive or curative aspects or even on its advisory side, involves a high skill and a heavy responsibility for the future as well as the present of the patient.

43 The remark of a lay house governor, Mr C E A Bedwell, which hardly deserves its position at the summit of the Ministry's argument might have been amplified by pointing out that it is the practically universal custom of hospitals (including Mr Bedwell's hospital) of referring to his insurance practitioner any insured person who attends hospital without an accompanying letter.

Proposed Extension of Medical Benefit to Juveniles

(Paragraphs 29-38)

44 In short, the suggestion of the Ministry is that for medical care upon young persons who have left school and entered insurable occupations, insurance practitioners should be remunerated at half the rate at present paid for adults. In view of this extraordinary proposal it is desirable to set down, as an illustration of the methods employed by the Ministry, the history of its various proposals on this subject.

(1) In November 1936 officials of the Ministry suggested to representatives of the Insurance Acts Committee as a basis of discussion a capitation fee of 6s for these new entrants into insurance. It was argued on the Ministers' behalf that his proposal was based firstly on the assumption that these young adolescents would make fewer demands on the services of practitioners than persons of older ages and secondly on the decision not to require certification.

(2) In December 1936 it was officially intimated on behalf of the Minister to the Insurance Acts Committee that he now offered a capitation rate of 7s 6d per annum. The official letter included the following sentence:

"While he [the Minister] remains satisfied that persons within the age group in question are likely having regard to their comparatively low sickness experience to make fewer demands on the services of practitioners than persons of older ages *he does not wish to press this point unduly since he recognizes that in the interests of public health it is desirable that juvenile workers should remain as far as possible under medical supervision* (Appendix I Ministry Memorandum)

(3) In January 1937 a further discussion took place between officials of the Ministry and representatives of the Insurance Acts Committee. No official offer was made to the Insurance Acts Committee but a proposal of which no doubt the Ministry's representatives will inform the Court, was made which if pursued, would have meant the payment of a full capitation fee for these young persons.

(4) Now in May 1937 the Ministry comes forward with a claim that 4s. 6d is the appropriate capitation rate for juveniles and 8s the appropriate rate for juveniles and adults alike.

45 It is desired to refer to the important principle involved in the suggestion that the young adolescent requires less medical care than the adult. It is an understatement to say that the Insurance Acts Committee is astonished to learn of the view of the Ministry of Health that the duties of medical practitioners in respect of these persons are less onerous and less responsible than for the insured community generally. The development of national health insurance in this country has been characterized by a growing recognition on the part of the community and the medical profession in particular, of the profound importance of preventive medicine, of the early detection of disease, and of the speedy and efficient treatment of apparently trivial complaints. The Committee had assumed that the outlook of the Ministry of Health had been expressed in such statements as the following, made by the Chief Medical Officer in his Annual Report for 1933:

"The insurance medical service is that branch of the public health services which under the terms of the National Health

Insurance Acts is concerned with the prevention and treatment of disease as it affects the individual members of the insured population. The importance of the service to the national endeavour towards raising the level of the health of the people as a whole and increasing the value of the life and capacity of each citizen can scarcely be over-estimated. The medical practitioners who provide the service by virtue of their opportunities for the early detection of disease in the individual form the first line of defence against communal disease and they provide also in most cases the best instrument for the prompt application to individuals of those preventive measures and improved methods of treatment which science puts at our disposal.

46 While the items of service which medical practitioners render to these young people are different in kind, they are *more* rather than less important than those rendered to older members of the community. While the conditions which bring the young adolescent to the doctor may, in some measure be classified on clinical grounds as minor, they are major in their importance to the individual and to the community. The Ministry's proposal to remunerate insurance practitioners at half rate for services rendered to these young adolescents would, if adopted, inevitably damage the national health insurance service as an important agency of positive health—as opposed to its function of healing established disease—and would definitely discourage insurance practitioners from giving to these young adults the full preventive and curative service which they need.

47 It should not be necessary to point out that the phase of transition from the sheltered years of school life to the early years of wage-earning is very commonly a difficult and trying one, when the friendly supervision of the family doctor is of paramount importance. The State ensures—and rightly so—that during school life the child is subject to careful medical supervision and the prompt treatment of defects minor and major. The suggestion that in the years that intervene between leaving school and attaining the age of 16 the need for medical supervision is not only less than that necessary during previous years, but also less than that which is necessary in the years which follow is an extraordinary one. Such a suggestion might be construed as an admission that the national health insurance system in this country is regarded by the Ministry of Health, not as an enlightened progressive agency to promote health and prevent disease but as a narrow restricted service concerned only with the treatment of established disease. It is a retrograde and reactionary proposal.

Mortality Rates

(Paragraph 31)

48 Of what value is the evidence afforded by the death rate of a group of persons of this age? The services rendered by a doctor to his patient are not more valuable because the patient dies. Nor is the service which is rendered in a killing disease more onerous than the service which is rendered in the encouragement of positive health in a patient who is well or practically so. Indeed, the skill demanded and the responsibility are the greater in the preventive and advisory work than in the treatment of the more dramatic manifestations of disease.

49 Admittedly the chance of dying at the age of 15 is one twentieth of the chance of dying at the age of 65. But the chance of living to be 65 is greater than it was even in 1924 largely as the result of an increased interest shared by insurance practitioners in the enlightened attitude (evidently not shared by the Ministry) to the health of insured persons.

50 It would appear from the use of this argument that the Ministry wishes to relate the insurance practitioner's remuneration for a particular group of persons to the death rate of this particular group. The Insurance Acts Committee can hardly be expected to object, provided the Ministry is logical and proceeds, on its basis of 4s 6d per head for the under 16 group, to pay a capitation fee of £1 1s per persons aged 50 and £5 17s for those aged 70.

51 The death rates afford no indication whatever of the responsibilities of the medical profession for this group. The distinguishing feature of much of the sickness experienced by the young adolescent is that it does not kill: tonsillitis, septic infections, minor accidents, ear infections, and skin diseases are examples.

Sickness Experience of Insured Persons

(Paragraph 32)

52 Analogous considerations apply to this argument. While the statistics for incapacity relate only to illness which incapacitates for longer than three days, the characteristic of much of the sickness which young persons experience is either that it does *not* incapacitate or that it does not incapacitate for longer than three days. This is perhaps one of the considerations which has led the Government not to include sickness benefit among the benefits to be available to those entrants to insurance. The Ministry refrains from adducing evidence for its suggestion but asks the Court to assume that the experience of incapacitating sickness at any age is a reasonably relative measure of the demand for medical services *'in the absence of proof to the contrary'*. This is a new method of offering evidence. Neither a lesser experience of incapacity lasting over three days nor a low death rate provides a measure, either reasonable or relative of the nature or number of the items of medical service rendered to young adolescents.

Services Rendered to Insured Persons under 19

(Paragraphs 34 and 35)

53 It is suggested by the Ministry that the *number* of items of service rendered to the under 16 'group' is less than those rendered to the adult community. Even if this were so it would be contrary to the interests of the community to encourage and perpetuate such a state of affairs by governmental action.

54 The criticisms advanced in the paragraphs of this statement relating to the number of services rendered by insurance doctors apply with particular force to the figures put forward by the Ministry in paragraph 34. The items of service rendered to juveniles are more commonly trivial as clinical manifestations of disease (although none the less important from the point of view of the patient's present and future health) and in consequence still less likely to be recorded as A's and V's.

55 The Ministry bases its calculations in regard to insured persons under 19 upon the lists of fifty-nine out of a total of 18,000 insurance practitioners. Figures relating to 2,883 persons between 17 and 19 are used as the basis for calculating a capitation fee for 1,000,000 persons of between 14 and 16.

56 Further the Ministry does not indicate that to these figures has been applied an important correction. It refers in paragraph 14 to the fact that new entrants into insurance, placed on the doctor's list during the year in question were excluded and in paragraph 21 states that, in view of its smallness no corresponding correction was made. But on the Ministry's own statement this correction would not be small for this group. It is stated in paragraph 33 that many persons do not place themselves on a doctor's list until they need treatment—a factor of far greater importance in the case of young entrants to insurance. By this method if a young person needing medical care and selecting a doctor for this purpose makes his choice from January 2 to December 31 his card with its high proportion of entries is discarded. If he made his choice in the previous year the items of service which were concentrated in the period of time immediately following the choice are not included—unless the patient made his choice of doctor in the last few days of the previous year. In short the method of

collecting statistics gives the least possible return of the items of service actually recorded.

57 The only reliable guide on the subject is the experience of general practitioners in actual practice and it will not be denied that the Insurance Acts Committee is well equipped to express an opinion. It is their experience that the number of items of service rendered to young adolescents in this age group is not materially less than the number of those rendered to the present insured population. By governmental and other propaganda this section of the community is being encouraged to seek the advice of the medical profession. To give an example of official encouragement to seek doctors' services it should be borne in mind that the widely accepted policy for improving physical fitness will add to the profession's responsibilities in respect of these persons. The young adult is looking more and more to his doctor for advice on minor troubles, an attitude which it is in the public interest to encourage and which, it is assumed, the Ministry of Health would desire to encourage in any extension of national health insurance. The act of including these persons in national health insurance will inevitably and properly have the effect of encouraging them to seek the help of their doctor in increased numbers.

Absence of Certification

(Paragraphs 35–38)

58 It is recognized that certification for national health insurance purposes will not be required of insurance practitioners for these entrants to national health insurance. Had certification been required it would not of itself prove a serious burden, for as has been pointed out earlier in this memorandum, the responsibilities of the insurance practitioner in respect of these persons is to a not inconsiderable extent preventive and advisory. The practitioner would have had less duties in relation to incapacity and more in relation to positive instruction on health and in the early detection and treatment of disease. Although he will not be required to undertake the actual filling in of national health insurance certificates, his responsibility in so far as certification is necessary for other purposes remains unchanged. For example, the employer will require certification of evidence of incapacity in most cases. Insured persons over 65 do not receive certificates to day and it has never been suggested that the capitation fee should be lowered because of this.

59 While the Ministry has withdrawn its original suggestion that there should be differential capitation rates it has introduced the argument that because on its calculation the numbers of items of service rendered to this new group are less than those rendered to the existing insured population the general capitation rate should be lower.

60 On the one previous occasion (in 1923, when old age pensions were not obtainable till 70) on which an additional group was introduced to national health insurance—that is, when medical responsibility for a number of persons over 65 was added—insurance practitioners were asked by the Ministry to accept these old persons, many of whom had been compelled by infirmity to give up work at the general capitation rate. Although the sickness liability for these persons was known to be well above the average of the insured community generally, the Insurance Acts Committee unhesitatingly accepted them at the current rate without special loading because it assumed it to be a fundamental principle of national health insurance that a flat rate should be applicable to all groups, and that excessive sickness incidence in one group might be balanced by a lesser incidence in another.

61 The Ministry's new principle has its implications. Older persons certainly require more items of treatment of a curative character than younger persons. The population as the result of the interplay of a number of factors including the work of insurance practitioners is ageing with some rapidity. The average age of the

population is greater than it was twenty years ago the number of insured persons over 65 increased by 44 per cent (from 873,800 to 1,257,300) between 1928 and 1935, a part of the period under consideration

62 To refer to curative items only, the addition of a group of young persons demanding fewer of these items will soon be more than counterbalanced by the items of service for the growing proportion of older persons in the community. The Insurance Acts Committee does not desire to reopen the question of the capitation fee every few years—whenever this proportion rises materially—but the acceptance of this principle would seem to necessitate this course

63 The Ministry assuming that 1,000,000 young persons would, by the Government's proposed legislation, be added to the existing insured population of 18,000,000, has converted a 4s 6d reduction in the capitation fee as a 3d reduction spread over the whole of the insured population. Assuming all the contentions of the Ministry to be sound this proposal would be equitable only if the proportion of the new age group to the existing age group remained 1 to 18

64 When the Ministry first discussed this proposed extension they anticipated that the number entering was likely to be in the region of 700,000. Subsequently, in an official letter of December 23, 1936 the Minister changed the estimate to 1,000,000, and at the same time referred to possible variations

The Minister also wishes to take this opportunity of informing you that he has found that the number of new patients who would be brought within the scope of medical benefit in Great Britain is owing to the recent increase in the employment of juveniles likely to be about 1,000,000 at the outset instead of 700,000 as intimated to the representatives of your Association. It will be appreciated however that the number is subject to variation for reasons dependent on the birth rate, and that in any case it will fall when the change in the school leaving age comes into force

65 The Ministry anticipates a definite and no doubt substantial fall when the change in the school leaving age comes into force, and refers to variations dependent on the birth rate. There is a third factor of considerable importance to which the Ministry does not refer. This is the "hump" in the birth rate curve, corresponding to the post-war babies, which is at present affecting this particular group. It is inevitable that there should be a substantial reduction in the number of persons of this age group in the community within the next few years. A capitation fee which is to apply to more than a single year should have reference to these prospective changes in the ratio of 1 to 18

Summary (Paragraph 38)

1 The Ministry, which has in the last six months suggested widely different capitation fees and has officially offered 7s 6d (rejected unanimously by insurance practi-

tioners) now offers a capitation fee of 4s 6d for the 'under 16' group

II The arguments on death and incapacity statistics are irrelevant

III The medical services rendered advisory, curative, and preventive, will be not materially less in number and nature, in the responsibility they involve and in their importance to subsequent life of the patient, than those rendered to adults. In any case it would be contrary to the national interest to pay half-rate, and thus convey the impression that a 'half service' is being provided for this important group of the insured community

IV The Ministry's figures are subject to important errors which invalidate them

V Any immediate lowering of the average age of the insured community will be adjusted comparatively soon because of the growing average age of the community generally

VI There is no case for paying less than the full adult capitation fee for young adolescents—despite the absence of certification

General Summary

(Paragraph 39)

A On a proper interpretation the Ministry's own returns show a 9½ per cent increase in the items of service given to insured persons. The Insurance Acts Committee returns show an increase of 33 per cent without weighting, and 36 per cent with weighting, justifying an increase in the capitation fee of 3s to 3s 3d, according to whether the Ministry's method of weighting is adopted or not

B The agreed basis of fall in cost of living justifies a reduction of 5d

C The figure adopted by the 1924 Inquiry for the ratio of gross expenses to gross receipts in a Type 2 practice was 25 per cent. The true ratio is shown to be 33 per cent. There should be a corresponding increase of 9d. The cost of locomotion is included in these figures

D There is no justification for the payment, in respect of "juveniles," of a capitation fee less than that payable in respect of the existing insured population

E Perhaps the least justifiable of all is the claim of decreased responsibility and less onerous service used by the Minister to justify the final reduction of one penny and the convenient figure of 8s. There has been a substantial increase in the responsibility borne by insurance practitioners

It is apparent that the Minister has strained every nerve and not a few figures so as to justify the suggestion that the capitation fee should be reduced to 8s

In the submission of the Insurance Acts Committee no capitation fee less than 12s 6d for all insured persons, including the under 16 group will provide adequate remuneration for the services rendered

REJOINDER OF THE MINISTER OF HEALTH AND SECRETARY OF STATE FOR SCOTLAND

1 The Minister of Health and the Secretary of State for Scotland (hereinafter referred to as 'the Ministers') do not desire to take exception to anything in the historical review of the situation contained in the Memorandum and they have no desire to offer any comments (even if they were within the terms of reference of the Court of Inquiry) as to the general standard of service given by insurance practitioners

2 The facts as to recent developments in medical science are substantially admitted but the Ministers as will be seen from paragraphs 22 to 28 of the second part of their Memorandum consider that the Insurance Acts Committee exaggerates their practical importance to the average

general practitioner and that, in any event, the net effect of these developments has been to reduce not to increase his work and responsibility

3 The increasing proportion of elderly people in the population is admitted but since any increase in medical work resulting from this change must be reflected in the statistics of services rendered there is no need to consider separately the effect of this gradual change of average age. It may be pointed out however that since 1926 certificates of incapacity have not been required for persons over 65 (the age limit for this purpose having previously been 70), but that practitioners have continued to receive the same capitation fee notwithstanding this relief in their duties

Statistical Evidence

4 The most important issue is clearly the extent to which the average number of services rendered in each year to each insured person on a doctor's list has increased since 1924. The difference between the figures submitted in the two Memoranda is striking and, it will be noted, is much greater in the figures for 1936 than in those for 1922. The figures in the two Memoranda purport to be a measure of the same phenomenon and the cause of their difference must therefore lie in the method of measurement. The Ministers have given in some detail the method followed in the collection of their statistics, and the steps taken to secure the representation of all types of practice and all parts of the country. They are satisfied, and will contend, that the methods adopted are such as to produce true average figures, and must therefore conclude that the comparison afforded by the figures of the Insurance Acts Committee is in some way faulty. It is, however, impossible to criticize these figures in detail until similar detailed information as to the methods adopted for their compilation is available from the Insurance Acts Committee, showing *inter alia* how the record keeping doctors have been selected (with evidence that they are a representative sample of the service as a whole) precisely what they were asked to enter on the special forms supplied, and how the number of insured persons to whom the aggregate services rendered by each doctor have been related, was calculated. It will, of course, be essential for the present purpose that the figures for 1936 should be properly comparable with those for the year with which a comparison is to be made. It is to be noted that the Insurance Acts Committee makes its comparison with the year 1922 and not with 1924 and that its figures for 1922 and those for 1936 have been collected from different sources. There is indeed a suggestion in paragraphs 11 and 12 of its Memorandum that the method by which the 1936 figures have been collected is claimed to produce a more accurate result than that used for 1922.

It may be admitted that though the practitioners selected for the purpose of the figures in the Ministers' Memorandum were chosen as being good record keepers, it is possible that they have not in every case kept perfect records of all services given by them but this does not vitiate the comparison with the year 1924 unless the accuracy of the official records was substantially different in 1924 and in 1936.

Reference to Regional Medical Officers

5 For 1935 the number of insurance practitioners in Great Britain was about 20,000 and the number of references to Regional Medical Officers was therefore on average approximately one every two weeks for each insurance practitioner. Further, in 30 per cent of the references the only report required of the practitioner is the entry on the form of the date on which he issued a final certificate to the patient (that is the date on which he certified that incapacity had ended).

Practice Expenses

6 The Ministers have no information by which to test the statement that practice expenses have increased. They submit that it is important to know the extent of the information on which this contention is based and how far it is typical of the average insurance practice.

Travelling Costs

7 It is not disputed that a motor car is necessary to the proper conduct of the normal general practice but the statement that the mileage involved in attendance on a given number of patients is increasing seems to call for comment in view of the increasing proportion of insurance doctors to insured persons particularly if the official statistics showing a decrease since 1924 in the number of

visits are accepted as correct. It appears important to know on what information this statement is based and to how many practices of what type, the information relates.

The information given by the Automobile Association is difficult to criticize in the absence of any statement as to precisely what the Association was asked to supply. The assumed cost of the car in each year is not given nor the method of estimating depreciation and neither of these items can be calculated without knowledge of the assumption as to annual mileage and the number of years for which the car is retained in use.

Certain of the figures supplied are, however, independent of such considerations, being directly proportionate to mileage covered, and of these the comparative costs for tyres for 1924 and 1936 seem open to objection. The cost of tyres has decreased and their useful life in miles has greatly increased. The Ministers' assumptions on this head are stated in their Memorandum. A paper in the March Journal of the Institution of Automobile Engineers by Mr. G. C. Williams, Director of Research to the Institution, discusses generally the effect of research on tyre life and states that mileages of 30,000 on private cars are now quite common and that there has been a tenfold improvement since before the war. The fall in tyre costs shown in the Ministers' Memorandum seems to be a very moderate claim.

The most serious criticism of the comparative figures given by the Insurance Acts Committee is, however, that they wholly omit any reference to the increased use of cars of lower nominal horse power, which is perhaps the most striking phenomenon in motoring in the period under review. Attention has already been called to the information on this point given by the Society of Motor Manufacturers and Traders. In 1924 cars of 10 h.p. or under formed less than a quarter of the total sales of British cars, in 1935 they were more than 60 per cent of the total. The Ministers submit that a contention that the motoring needs of the insurance practitioner differ so fundamentally from those of the average motorist that the same type of car can properly be taken for the two years is inadmissible without definite proof.

Further, such positive information as is available to the Department is inconsistent with the basis of the Insurance Acts Committee's comparison. At intervals of four years records of travelling (for purposes connected with the Mileage Fund mentioned in paragraph 18 of Part I of the Ministers' Memorandum) are kept by a number of doctors in rural and semi-urban practices. These doctors are typical of those who receive payment from the Mileage Fund and therefore, may be presumed to need cars of rather higher power than the average insurance practitioner but in 1936 out of about 400 cars used by these doctors 252 were of 12 h.p. or less and the three largest groups were 10 h.p., 12 h.p. and 14 h.p., there being 96, 92 and 52 respectively in those groups. The average horse power of the 400 cars was 12.

The comparable figures for 1924 are less complete since the horse power was less often given but out of the total of 318 there are 256 of which the horse power is indicated. Of the 256 115 were of 12 h.p. or under and 141 were of higher power. The average horse power of the 256 was 15. It may be mentioned also that in 1924 there was an appreciable proportion of American or Canadian cars of high horse power and that there are few such cars in the 1936 list. (The general importation of foreign cars has fallen since 1924 according to the diagram on page 44 of the publication of the Society of Motor Manufacturers and Traders mentioned in paragraph 12 of Part II of the Ministers' Memorandum.)

The Young Adolescent

8 It is suggested at the end of paragraph 21 of the Insurance Acts Committee's Memorandum that the absence of certification for this class is the only factor that need be

taken into account, but this contention is not explicitly put forward, nor is it accepted by the Ministers. It is of course true that this age, roughly from 14½ to 16, is a period important for future health. It does not follow that this age requires more treatment than another, or that in practice persons in this group will demand or receive more treatment. The Ministers have therefore confined their argument to the consideration of such facts as are available.

As a minor point it should be noted that an insurance practitioner would be entitled to charge for any certificate of incapacity required by the employer of a juvenile.

9 In regard to paragraph 22 of the Insurance Acts Committee's Memorandum, it will be apparent from what is said above and in their Memorandum that the Ministers do not accept the arguments leading to the figure of 11s 1d., or the assumptions of the Insurance Acts Committee as to the net effect of advances in medical science, but apart from those questions, the increase from the calculated figure of 11s 1d. to the claimed fee of 12s 6d., unsupported by any measurable facts, appears to be purely arbitrary.

10 In conclusion, therefore, the Ministers see no reason to depart from the submission in their Memorandum that, so far from there being ground for any increase in the capitation fee, a reduction from 9s to 8s would be justifiable.

General Council of Medical Education and Registration

SUMMER SESSION 1937

The one hundred and forty-fifth session of the General Medical Council was opened at Hallam Street, W, on Tuesday, May 25, Sir NORMAN WALKER presiding.

Mr Harold Collinson, F.R.C.S., appointed as representative of the University of Leeds for three years from August last, was introduced and took his seat.

PRESIDENT'S ADDRESS

Sir NORMAN WALKER then addressed the Council as follows:

Since last we met two former members of the Council have passed to their rest. John Theodore Cash represented the University of Aberdeen here from 1911 to 1919. His expert knowledge led to his early election as a member of the Pharmacopoeia Committee, to which he gave devoted service. Sir Grafton Elliot Smith was chosen by the Victoria University of Manchester as its representative in 1913 and resigned in 1919 on his appointment as Professor of Anatomy in the University of London. He was an active member of the Council on its educational side, and he and John McVail were prime movers in promoting the last revision of the curriculum. Sir William Hansell served as our much esteemed Legal Assessor from 1920 till 1927 when his promotion to judicial office compelled his resignation. He died on April 18, 1937.

A vacancy has been caused among the Crown nominees. We would have welcomed the news of his reappointment, but Sir Henry Dale found that his many other engagements would make it difficult for him to find the time which he felt the Chairmanship of the Pharmacopoeia Committee required. We cannot let him go without an expression of our gratitude to him for so successfully guiding the early steps of the Council in their close and cordial association with the British Pharmacopoeia Commission.

We offer our congratulations to Sir Kaye Le Fleming, on whom the honour of knighthood was conferred in the first Honours List of the new reign and trust he will be long spared to enjoy it.

Our Junior Treasurer Mr Eason who has represented the University of London here since 1924, has been chosen

by his University to be its Principal. We congratulate him on the distinction, and wish him success in the discharge of his honourable and arduous duty.

Business of the Council

It is enjoined by tradition upon those to whom it falls to prepare the business of the Council for consideration at their sessions to endeavour to arrange that the summer session shall be primarily devoted to the first object of the Council's existence, medical education, and that they shall deal with disciplinary cases, as a Council of Medical Registration, mainly at the session in November.

But in recent years, at any rate, it has seldom been possible to achieve this aim, because the Penal Cases Committee are not in a position to regulate the numbers of cases of convictions of registered medical practitioners reported, or of complaints made, to the Council, which in their judgement call for the holding of inquiries before the Council at the next ensuing session.

On this occasion, fortunately, circumstances seem more favourable than they sometimes are, and though a substantial number of disciplinary cases await your consideration, none appears likely to be exceptionally lengthy, and time should be available within the week for ample discussion of the reports of the three committees whose work lies in the sphere of medical education.

Medical Education

The report which will call for the fullest consideration is that of the Education Committee, who have been dealing with the concluding stages of the revision of the curriculum initiated in 1934.

There has been a little variation in method, though not in principle, in the procedure adopted on this occasion. Instead of leaving the matter to the Education Committee, as was usually done in the comparatively recent past, the Executive Committee recommended to the Council the appointment of a special Curriculum Committee composed of the chairmen of the three standing committees on education, examination, and public health, who were individually recognized as authorities on physiology, anatomy, and public health, with the addition of a physician, a surgeon, an obstetrician, and a member engaged in the general practice of medicine.

The Council adopted the recommendation on June 2, 1934. The Committee elected Dr Tidy as their chairman, and commenced work at once, reporting progress to the Council in November, 1934, and making interim reports in May and November, 1935.

Constant communication with the licensing bodies was maintained, and most of the deans manifested their interest in, and their criticism of, some of the proposals made. As time went on, and all who are familiar with the working of the Council know that in reform of the medical curriculum it is wisest to hasten gently, the true meaning of a reform of the curriculum was more and more understood.

This Council is a team composed in the first instance of a representative from each of the licensing bodies. To these are added five nominees by the Crown and seven practitioners elected by the direct vote of the profession in each of the three divisions of the United Kingdom.

To the Council is committed a general supervision of medical education, and in their early days perhaps the licensing bodies were the only persons actively interested. Admission to the Register was easy in 1858 but in process of time by general agreement among the bodies, the minimum curriculum was fixed at three winter and two summer sessions. Then came four years and in 1890 the Council unanimously approved an extension to five years afterwards modified to fifty-seven months, mainly because university years were usually of nine months.

On no previous occasion have the proposals of the Council been more thoroughly hammered out on the anvil.

of discussion and a large measure of agreement has apparently been reached. Thus with certain reservations there seems to be approval of the age of 18 for registration of students.

Chemistry, Physics, and Biology

The question of biology, chemistry, and physics has always been a problem, and I remind the Council that it was only in 1893 that the Council ordained that the first and last of these subjects *must* be contained in the medical curriculum. Chemistry was defined then as "including the principles of the science and the details which bear on the study of medicine." In 1893 in most parts of the country the teaching of chemistry and physics in schools was of an elementary character, and biology only appeared in the curriculum of one or two of them. Times have changed, and the chemistry and physics taught in the majority of the schools is of high standard, even if it does not include any "details which bear on the study of medicine." These must of course be learned in medical schools. The teaching of biology of a sufficient standard has not advanced so far as that of the other two subjects. Schools capable of undertaking it are not uniformly scattered over the British Isles, and there is a feeling in some quarters that the minds of some young people are perhaps too much devoted to the study of those three subjects to the detriment of their general education.

Here we are helped by the elasticity of our system. If we agree, in order to furnish the requisite knowledge and skill for the efficient practice of the profession that the medical curriculum proper requires to be extended to five years, the licensing bodies (all represented here) will frame their regulations accordingly. Already Birmingham, Bristol, Liverpool, Manchester, Oxford, Wales, and University College Galway, require six years, Cambridge, Leeds, London, and Sheffield five and a half, and it is common knowledge that others have in contemplation an extension of their curricula. This is the way in which medical education in this country progresses. The Council prescribe a minimum below which no body which wishes to retain its right of admission to the Register may drop, but has nothing but a Well done for those bodies which raise the standards for admission to their own degrees.

Statistics

I have to report that the number of medical students registered by the Branch Councils in 1936 was 2,544, 59 less than in 1935, this figure resulting from decreases of 82 in England and 9 in Ireland and from an increase of 32 in Scotland, and that the number of names added to the *Medical Register* by registration in 1936 was 1,905, 123 more than in 1935. The net increase in the number of registered medical practitioners at the end of the year after deducting the numbers of names removed from the Register by reason of death and on other accounts was 649, and 59,010 practitioners remained on the Register at the end of the year, not far short of 1,500 more than the average number at the end of the last five years.

Finally, I may note that the Chairman of the Finance Committee, in presenting to you the Committee's Report on the annual accounts for 1936, will have the satisfaction of stating that there was a surplus of income over expenditure for that year of more than £2,500.

With perhaps one forenoon session the prospect of concluding our business on Friday seems good.

Mr. HEN GROVES proposed and Dr. MOORHEAD seconded a vote of thanks to the President for his address, and this was carried.

On the motion of the President Sir Robert Bolam was re-elected Chairman of Business.

The Council then proceeded to consider certain charges against dentists on reports and findings of the Dental Board.

ANNUAL REPRESENTATIVE MEETING, BELFAST, 1937

The Annual Representative Meeting of the British Medical Association will be held in the Assembly Hall, Assembly Buildings, Fishers Place, Belfast, on Friday, Saturday, Monday, and Tuesday, July 16, 17, 19, and 20, 1937.

RESOLUTIONS BY DIVISIONS AND BRANCHES FOR THE REPRESENTATIVE BODY

DUTIES OF AND ETHICAL RULES FOR INDUSTRIAL MEDICAL OFFICERS

Motion BY COUNCIL (para. 89 of Annual Report of Council). That the statement of the duties of industrial medical officers and the ethical rules relating to such officers be approved. (See Appendix IV to Annual Report.)

Amendment BY NOTTINGHAM. That para. 1 (vi) of Section II (Ethical Rules) Appendix IV, be amended by the deletion of the words "after communication with the workers' medical attendant" and the insertion after "dangerous occupations" of the words "and shall communicate with the worker's own medical attendant at the earliest opportunity."

The paragraph as amended would read:

(vi) The industrial medical officer shall (a) examine and advise concerning those workers engaged in hazardous or arduous occupations, also those about to be transferred to heavy or dangerous occupations, and shall communicate with the workers' own medical attendant at the earliest opportunity, and (b) examine and report to the works management upon those workers who appear suitable for early pension or retirement or in regard to the continuance of invalidity payments.

MINISTRY OF HEALTH CIRCULAR 1550 ON CHILDREN UNDER SCHOOL AGE

Motion BY BLACKBURN. That, with reference to para. 105 of the Annual Report of Council, the duties of health visitors should be strictly defined and limited, and that legal opinion should be taken as to whether the giving of advice and/or treatment by health visitors without medical instruction or supervision constitutes unqualified practice.

LECTURES TO FINAL YEAR MEDICAL STUDENTS ON INTRA-PROFESSIONAL CUSTOMS AND OBLIGATIONS

Motion BY BIRMINGHAM CENTRAL. That the Council be requested to approach universities and other teaching bodies with the view to establishing lectures for final year medical students to instruct them in intra-professional customs and obligations, and that the lecturer be one who is well versed in the Association policy.

OFFICE SECRETARY FOR ANNUAL MEETINGS

Motion BY PLYMOUTH. That in view of the intricacy and amount of administrative work entailed in connexion with the organization of an Annual Meeting the services of a trained office secretary are desirable. He (or she) should be a whole-time official of the Association to take up duty in October of the year immediately preceding the Meeting and after a period of leave return to clear the outstanding matters and assist the honorary local general secretary in the preparation of his report. He (or she) will then proceed to the Branch or Division in whose area the Annual Meeting next following is to be held. The employment of such an official would result in an economy to the Association and to the local Division or Branch as much duplication of printing postages etc., would be obviated. If necessary, the grant from central funds towards the expenses of the Annual Meeting could be reduced proportionately.

Correspondence

DISPENSING CAPITATION FEE

SIR—If Dr H F Burt would look further into the matter of his letter (*Supplement* May 22, p 308) I think he will find he is losing a great deal more than the 5d he speaks of for while he gets a discount of at the most, 10 per cent on the price of his drugs, the "chemist" has not less than 33 per cent—I am etc.,

varying effects on voluntary movement. Comment on these results must be reserved until fuller particulars are published, but it is already clear that further experimental and clinical investigation of the subject may lead to conclusions of theoretical and practical importance.

ROCKEFELLER MILLIONS

"Giant, dwarf, symbol" is the subtitle of one of the many biographies of John D Rockefeller, who has died in Florida at the age of 97, and it expresses the astonishing contrasts in his personality and achievements or the public estimate of them. To an earlier generation, which saw the rise of the Standard Oil Trust, his was a sinister countenance brooding over American industrialism, signifying relentless business and the evils of monopoly. As time went on the countenance changed to one of wise benevolence, the name of Rockefeller came to stand for philanthropy on the heroic scale, and the man became a legend. His system of benefactions went far beyond his own country, to the extension of the Bodleian at Oxford, for example, the restoration of the cathedral at Rheims, the endowment of the Imperial Library at Tokyo. Every country of the British Empire has benefited largely from his gifts. It is nobody's business in particular to decide whether the credit of his later benevolence balances the debit of his "predatory capitalism," but no one can question that the Rockefeller millions have contributed vastly to human happiness and well being. It is estimated that the total amount bestowed by him on educational and philanthropic causes exceeds one hundred and fifty millions (pounds, not dollars). To Chicago University alone his gifts ran to seven millions.

Rockefeller planned his philanthropy with the same organizing skill as had given him control of the oil industry. He brought it mainly within four corporations managed by hard-headed business colleagues. The first was the Rockefeller Institute for Medical Research. This arose out of a gift of £40,000 made by him in 1901 not for the building of a research institution, but for the purpose of ascertaining what young men were available in the universities for pursuing medical research with a view to furnishing them with grants and fellowships. The information was acquired more quickly than had been anticipated, and in 1902 the idea of a research laboratory in New York took shape and in the following year Simon Flexner was persuaded from his university chair to become director of the enterprise—the first of many instances of the way in which Rockefeller cast a spell over the best brains available and

brought them into his service. Under Flexner's leadership the research institute came to exercise a profound influence on American medicine. It was fed by successive gifts from Rockefeller, amounting in all to eleven million pounds. The second great corporation was the General Education Board, subsidized from Rockefeller moneys to the extent of twenty-five millions, for the promotion of education in the United States, and the third was the Laura Spelman (Mrs Rockefeller) Memorial, which received fourteen millions, and chiefly concerned itself with child welfare and social science, this has now been consolidated with the Rockefeller Foundation.

The Rockefeller Foundation, the outstanding philanthropical body of this or any time, was established in 1909 as a great clearing house of humanitarian effort, with an initial gift of twenty million pounds, the largest single gift ever made, and since then nearly doubled. In the International Health Division of the Foundation from 1913 to the end of 1935 over eleven million pounds was expended. State and local health services in many countries, including public health administration, vital statistics, epidemiology, public health laboratories, sanitary engineering, and bureaux for the study and reform of public health activities, have absorbed much more than one million, and the control of tropical diseases, especially yellow fever, hookworm disease, and malaria three millions. On the building equipment, and endowment of schools and institutes of hygiene and public health three and a half million pounds has been spent, of which nearly half a million has found its way to this country. India has received princely gifts from the Foundation. Large allocations have been made to the health work of the League of Nations, without which many of its social activities, particularly in the Far East, could not have been initiated or carried on. From Fiji, where the central medical school at Suva has received £15,000, to the Caribbean Littoral and the Amazon Valley, where many thousands have been spent on the control of yellow fever alone, there is hardly a land which has not benefited. Rockefeller gifts to English universities have included large sums to Cambridge, London, and Bristol—but the recital of millions can become stupefying and monotonous.

John D Rockefeller multiplied his years as he had multiplied his fortune. At 90 he determined to live to 100 by careful conservation of his bodily resources and strict scrutiny of his meagre diet, but it is said that within the last year or two he abandoned this ambition feeling that a life of feebleness and inertia was not worth prolonging and he died a little more than two years short of his century. Had he lived in past ages his memory

would now be invested with all kinds of superstitions. How posterity will regard him no one can say, but his benefactions will continue and will be his memorial. He rests from his labours and his carefulness, and, in an arithmetical sense not conceived by the seer of Revelation, his works do follow him.

PREVENTION OF POLIOMYELITIS BY NASAL SPRAYING

The unpromising results of field trials in the serum prophylaxis of poliomyelitis have stimulated a search for effective measures along other lines. Experimental work leaves little doubt that the virus gains access to the body by the nasal cavity, invades the terminal processes of the olfactory nerves, passes up the axis cylinders to the brain and thence spreads to the anterior horn cells of the cord, where the chief lesions are produced. If the entrance of the virus to the olfactory hairs could be blocked it might be possible to protect the central nervous system from invasion. Armstrong Harrison and various other workers in the United States recently brought forward evidence to show that in monkeys the nasal instillation of such substances as alum and picric acid may protect the animals against subsequent inoculation with the viruses of poliomyelitis and encephalitis. The results were so satisfactory that it was thought justifiable to try this method on the human population. The outbreak of poliomyelitis in Alabama last summer afforded the opportunity to carry out a field trial on a fairly large scale. By enlisting the help of the local doctors and advising them how the treatment should be conducted widespread interest was created with the result that about two million persons were sprayed in the three States of Alabama, Mississippi and Tennessee. The solution used consisted of 0.5 per cent. picric acid and 0.5 per cent. sodium aluminium sulphate in 0.85 per cent. saline. The directions were that three or four puffs from an atomizer directed towards the top and not the back of the head should be blown up each nostril. Spraying every other day for a week and once a week subsequently for the duration of the epidemic was recommended. Collection of the results at the conclusion of the outbreak proved very difficult. It was clearly impossible to obtain data from the total sprayed and non-sprayed population. A sample therefore was selected for study in the Birmingham and Jefferson county area of Alabama. Of 5,097 white persons interviewed 69.7 per cent. had received spray treatment and of 2,996 coloured persons 48.9 per cent. had been treated. The length of time during which the treatment had been given was taken into account and the total number of weeks of exposure to risk of sprayed and non-sprayed persons was calculated. During the period July to September 1936 the actual number of sprayed cases developing poliomyelitis was fourteen in the sample of the white population examined and two in the sample of the coloured population. The calculated numbers that would have developed if the incidence in the sprayed had been the same as in the

non-sprayed portion of the population were 16.8 and 4.9 respectively. It will be seen that the advantage of the treated group was not great. This may to some extent have been due to the inadequate nature and duration of the spraying in a proportion of the subjects. Inquiry showed that the spray was not entirely innocuous and that about 20 per cent. of those treated suffered from headache, nausea or local irritation of the nose and throat. We recently¹ drew attention to the possible risk of permanent damage to the nasal mucous membrane and this perhaps has not received full enough consideration. Reviewing these results Armstrong whose report² is here quoted, concludes that the ideal solution and the most effective method of applying it have not yet been found. The experience hitherto gained seems, however, to justify further attempts to improve this method of prophylaxis.

NAEVUS SEBACEUS

Dr. Pautrier³ has recently drawn attention to a type of naevus which is probably much commoner than the infrequent references to it in dermatological literature would lead one to suppose. This is the naevus sebaceus and the reason it so often escapes notice is that as its name implies it is mostly found where sebaceous glands are especially numerous—that is on the scalp, where it is concealed by the hair. As it gives rise to no symptoms patients do not often complain of it to their medical advisers. It consists of a conglomeration of sebaceous glands increased in number and size but of normal structure; they unite to form a superficial lesion with an irregular surface. It must be distinguished from the well-known adenoma sebaceum of Pringle which is a symmetrical eruption extending across the nose and cheeks and always exhibiting a strong angiomatic element; it is not really an adenoma of the sebaceous glands at all. Apparently the first dermatologist in France to describe the naevus we are now discussing was Audry, but only since 1929 have many cases been described and these reports for the most part emanate from a small number of clinics. It is therefore highly probable that the lesion is less rare than is supposed and that if sought for it would be found much more frequently. Dr. Pautrier himself in the course of the last four years has collected six cases which he has described in detail. As a rule the development begins within a few weeks of birth but sometimes later. It is most often found on the scalp but occasionally on the face. It scarcely ever exceeds five centimetres in diameter and the edges are clean cut but sinuous. The surface he describes as "légèrement bosselée" perhaps best translated as resembling a mass of pins heads closely set together. Even when the naevus occurs on the scalp very few hairs are found upon it. Microscopically it consists of an enormous growth of sebaceous glands quite normal in character except for their size. A further point of interest in the study of the naevus sebaceus is the light it throws on the aetiology of a

more serious type of neoplasm, the epithelioma sebaceum. Only recently has it been admitted that an epithelioma can arise from a sebaceous gland. For many years Dr Darier, the leader of French dermatology, refused to acknowledge the possibility. At length, however, the weight of evidence proved too strong even for him, and the article by Favre on malignant tumours of the skin in the *Nouvelle Pratique Dermatologique* gives an adequate description of epithelioma sebaceum. Among the cases described by Dr Pautrier is one in which on a typical naevus sebaceus of the scalp, congenital in origin, appeared two small nodules about the size of a green pea with a slightly excoriated surface. A biopsy proved that one nodule was a basocellular epithelioma—in other words a rodent ulcer—while the other was a typical sebaceous epithelioma. The sections have been examined by Civatte, a faithful disciple of Darier, who was thereby convinced of the existence of a sebaceous epithelioma, and by Favre, who wrote that they provided the clearest possible demonstration that a basocellular epithelioma such as in this country is still commonly designated rodent ulcer may arise from a sebaceous gland.

HUGHLINGS JACKSON—OPHTHALMOLOGIST

When a physician declares that the luckiest thing in his medical life was the study of ophthalmology, modest ophthalmologists may feel that an excessive charity permeates that belief. When the same physician declares, too, in connexion with a certain ophthalmological problem that it "may be studied at once with too much intensity and too little breadth" it is apparent that his is a critical mind surveying not only the scope but also the limitations of ophthalmology. This critical appreciation of a struggling specialty was Hughlings Jackson's contribution to ophthalmology. Jackson's medical life began a few years after the introduction of the ophthalmoscope in 1852 and if nothing in particular can be named as being his special contribution to a developing clinical study, he must be given credit for what is perhaps greater than a single eponymal contribution—method and orderly application. The first flush of thrilled surprise that the ophthalmoscope must have brought to those who took the trouble to master the elaborate technique required in using the early models of this instrument and the appreciation of the wider possibilities that it opened up not only for the study of the interior of the eye but for general medicine were experiences that Jackson shared with many of his contemporaries. He was outstanding, however, in his steadfast loyalty to that early vision. His broad view, his detailed survey and his perseverance over well nigh half a century preaching a gospel that must have seemed an unbalanced enthusiasm in its early days and an unbalanced devotion later on, and which yet gained appreciation in a generation that has grown up since his time—such was his achievement. That he had a message for ophthalmologists not only in his own day is clear from the bibliography of nearly ninety papers on ophthalmology which Burton Chance has listed in a recent appreciation.¹ In season and out

Jackson chastised the ophthalmologist who only "dwells with exaggeration—hurtful to his own organization of medical knowledge—on amaurosis as a defect of a highly specialized part of universal sensation." His message to physicians was no less explicit, and is unfortunately almost as valid to day as it was in his own time. "I believe that physicians are sometimes guilty of overrating slight appearances, finding something extraordinary where there is nothing particular and this naturally provokes the scorn of ophthalmologists and brings a valuable means of research in medical cases into contempt." It was inevitable that Jackson's contributions should have dealt with things that must now be regarded as elementary knowledge. That he should have made mistakes was also inevitable, but the manner in which he made his mistakes exemplifies the saying that great men are admirable even in their blunders. Though he devoted much attention to papilloedema and put forward theoretical views on the subject, he did so with that real modesty which distinguishes between an hypothesis and a conclusion. "an hypothesis is not a conclusion, it is only a provisional conclusion, something to be proved or disproved." That his own hypothesis has proved fallacious is of less significance than the fact that, just because it was not dogmatic, his hypothesis was useful in the elucidation of further knowledge. His paper on eyesight and tabes, read before the Ophthalmological Society in 1881, recounted nearly all on the subject that is now everyday knowledge, as solid observations and as a unity they were new then. To give the ephemeral permanency to distinguish between the false and the true in what was new to act in the present with a sense of the future—all these Hughlings Jackson contributed not only to neurology but to medical ophthalmology also. His plaint that it took twenty-five years for a truth to penetrate medical practice was no *bon mot* but was a characteristic expression of his outlook. By precept, teaching and example he helped to lay the basis of medical ophthalmology. Some of his observations and interpretations may not have stood the test of time, what is timeless is his contribution of a method of clinical study enriching general medicine no less than ophthalmology.

INTERNATIONAL UNION AGAINST CANCER

Twenty one different countries sent delegates to a meeting of the General Committee of the International Union Against Cancer which took place in London over the week end. They were entertained to luncheon on Saturday by the Executive Committee of the British Empire Cancer Campaign and on Saturday evening they were invited by H.M. Government to a dinner at Lancaster House, at which Sir Kingsley Wood presided (see p. 1131). The chief business discussed by the delegates was the programme for the next International Cancer Congress which it was decided should be held at Atlantic City in September 1939. The two official British representatives on the General Committee are Dr W. Cramer and Mr Cecil Rowntree, from whom further information can be obtained.

FOULING OF THE ATMOSPHERE

Dr G. M. B. Dobson, F.R.S., chairman of the Atmospheric Pollution Research Committee winds up his report for the twelve months ended March 31 1936¹ with a review of the state of the atmosphere during recent years. As he says the publication of a large mass of figures serves little useful purpose unless at the end of a number of years some definite conclusions can be drawn from them regarding the changes which are taking place in the purity of the air of the towns throughout the country. Account must be taken of the great industrial depression of 1930-3 in any attempt to discover whether propaganda and legislation designed to reduce fouling of the atmosphere have been effective. With returning industrial activity the amount of fuel burnt has increased, so that if the standard of efficiency remained constant an increase is to be expected. A small improvement in methods of combustion of coal may well be masked by an increase in the amount consumed. Though it is not possible to get very precise figures of coal consumption the results now available—at some stations going back to 1915—give ground for belief that the smoke abatement campaign has had a real effect. The outstanding feature of the curves is the large decrease in pollution observed at many stations before the depression began. The ratio of the amount of sunshine recorded at Kew Observatory and in Central London has been used as a rough measure of the amount of pollution in London. Analysis of these figures shows that since 1881 the percentage of winter sunshine in London compared with that at Kew has risen from 20 to 52—a very marked improvement. Reviewing the data as a whole Dr Dobson concludes that there has been a definite reduction in the extent of pollution of the atmosphere in Britain during the past twenty years.

THE MIDHURST REPORT

The thirtieth annual report from the King Edward VII Sanatorium Midhurst² provides material for reflection. The classification of patients has been modified but still appears to be unsatisfactory. The patients are divided on admission into three groups according to the Turban Gerhardt classification which is based on physical signs. How misleading this can be is seen from what follows. Each of the groups was further subdivided into patients with negative sputum and those with positive sputum. In group II the corresponding numbers admitted were then eighty-two and thirty-six respectively and even in group III as many as twelve out of thirty-eight had negative sputum on admission. Moreover in group II out of the eighty-two sputum negative patients forty-one were discharged "arrested" of the thirty-six sputum positive cases only one. It is justifiable to conclude that there must be something wrong either with the method of classification or with the methods of examining the sputum. As the latter is unlikely at Midhurst where the sputum is even cultured it is to be assumed that the condition of the sputum

"on admission" really means condition before admission. Incidentally the use of the term "arrested" is perhaps not happy for according to the definition given in the report what is really meant is "quiescent". It might be better to stick to the classification of the Ministry of Health since many of the patients when discharged from Midhurst return to tuberculosis officers who are compelled to use it. Attention may also be drawn to the fact that no fewer than sixty-one out of the 109 patients who on admission had tubercle bacilli in the sputum were still sputum positive on discharge. It would therefore be of interest to have amplified the statement that "during the three months after discharge most of the sputum positive cases (excluding those who are moved because of rapidly advancing disease) have entered the second category"—that is "their sputum has dried up or been three times negative to exhaustive tests". The most interesting parts of the report are those which concern special forms of treatment. Of the twenty-one patients who had an artificial pneumothorax induced at Midhurst seven were discharged with tubercle bacilli still in the sputum. Of forty-nine patients with positive sputum treated with sanocrysin the bacilli disappeared in no fewer than twenty-five. This may be considered as showing that sanocrysin "has a definite place in the treatment of pulmonary tuberculosis". The most marked results, however, are those obtained after operations on the phrenic nerve in suitable cases (which includes ineffective pneumothorax not lending itself to adhesion section) of fifteen patients with tubercle bacilli in the sputum only three remained sputum positive and this in spite of the fact that in half the patients only the "crush" operation was done. (Last year only three cases out of twenty-seven phrenic interruptions were submitted to the crush operation.)

THE CAPITATION FEE INQUIRY

The Court of Inquiry appointed by the Government to consider the Insurance Acts Committee's claim for an upward revision of the capitation fee began its investigation on Wednesday last, May 26, at the offices of the Ministry of Health the proceedings being open to the public. Statements of evidence prepared by the Insurance Acts Committee and the Minister of Health and the Secretary of State for Scotland and rejoinders thereto have been exchanged. These four documents are reproduced in our *Supplement* this week (p. 313). The Chairman of the Court is Lord Amulree who has presided over a large number of Government committees of inquiry and has acted as arbitrator and conciliator in industrial differences for the Board of Trade and the Ministry of Labour. The other members are Mr. Thomas Howorth, a chartered accountant and member of the firm of Price Waterhouse and Company, and Mr. D. H. Robinson, Reader in Economics in the University of Cambridge and a member of the Economic Advisory Council.

We publish this week at page 1134 an influentially signed letter inviting support for an endowment fund to establish a lectureship in pathology as a memorial to the late Professor E. H. Kettle M.D. F.R.S.

MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY

The annual meeting of the Medical Sickness, Annuity and Life Assurance Society was held at the offices, 300, High Holborn, W.C., on May 10

The chairman of directors, Dr F C MARTLEY reported a very satisfactory result of the actuary's valuation of the society for the four and a half years ending on December 31, 1936. He said that the total surplus as shown in the report on the sickness and the life assurance funds amounted to £225,639 of which it was proposed to distribute £153,000 as bonus and to carry forward the remainder. A most detailed and stringent examination and valuation of the liabilities had been made in view of the financial and economic difficulties through which the whole world had been passing every known contingency had been provided for and having taken all wise precautions the Board found itself in the happy position of being able to recommend the payment of a higher rate of bonus all round by increasing it from 12s to 15s per annum on the main classes of sickness policies for each guinea per week insured and from 23s to 25s per annum on the life assurance side for each £100 insured, together with a bonus on all combined policies at the same rates as if separate policies had been effected for the two benefits. The directors congratulated the members on the excellent figures which had emerged from this most careful and cautious valuation.

Dealing with the results of the year under review Dr Martley said that on the life assurance side the new sums assured amounted to close upon half a million. The total premium income in this department was now £111,856. A large proportion of the total premiums was in respect of the deferred annuities under the scheme which the society was assisting in operating for members of the British Medical Association and national health insurance practitioners. The society's family provision policy was proving very popular. Its chief advantage was that at the age of 60 the premiums paid did not disappear without any return but a guaranteed sum was payable when that age was reached. There could be no doubt that the most useful life assurance policy for members of the medical profession was the ordinary endowment assurance under which the sum assured was payable at death or on attainment of a fixed age. It was not easy for the medical man faced with family and practice expenses, to save consistently by way of investment and even if it was it was not always sound unless he happened to be a financial expert but there was no danger of depreciation in a life assurance policy effected with a sound company and if it was a with profit policy the assured had the pleasure of receiving bonus notices every quinquennium adding to the value of his investment.

On the sickness fund the new annual premiums totalled £10,702, which constituted a record. The premium income on this fund amounted to £108,637. It was an astonishing thing to him that members of the medical profession still went outside the society to obtain permanent sickness insurance. Its rates were not only lower than were obtainable elsewhere but it paid a bonus at the normal termination of each contract. The expenses of management were just over 9 per cent of the premium income and represented a reduction on previous years. Dr Martley concluded with a special word of appreciation of the staff.

The meeting unanimously adopted the report of the directors, re-elected the directors who retired by rotation (Dr W Knowsley Sibley and Mr R J McNeill Love) adopted the recommendations as to payment of reversionary bonuses in accordance with the actuary's suggestions, and agreed to a resolution for the payment of an interim bonus on all with profit policies for permanent sickness and accident insurance and life assurance becoming claims during the year.

Sir William Willcox moved a vote of thanks to the chairman, and referred to the great amount of time and business knowledge which he placed at the disposal of the society. This was seconded by Dr G de Bec Turtle and carried with applause.

On November 11, 1936 the subscribers to the memorial to Sir Walter Morley Fletcher were invited by the Medical Research Council to view Miss Dora Clarke's posthumous portrait bust. The ceremony was held at the National Institute for Medical Research, Hampstead, in the library of which the bust is permanently placed. A full report of the proceedings (over which Lord Balfour of Burleigh chairman of the Medical Research Council, presided) with the text of the addresses by Professor G M Trevelyan and Sir Frederick Gowland Hopkins, has now been printed for the trustees of the memorial fund by the University Press Oxford and the list of subscribers appears as an appendix. This forty page pamphlet with its two photographs of the bust, will be welcomed by all Walter Fletcher's friends and admirers, and is an excellent piece of typography.

Reports of Societies

DISEASES OF THE COLON

At a meeting of the Subsection of Proctology of the Royal Society of Medicine on May 19, with Mr G GORDON-TAYLOR in the chair, Sir EDMUND I SPRIGGS of Ruthin Castle opened a discussion on the incidence and treatment of diseases of the colon.

Sir Edmund Spriggs proceeded to analyse from a very large number of consecutive cases of various diseases 1,574 cases in which there was some affection of the colon which might be described as a disease or disorder, and he also mentioned 1,520 other cases in which there was delay in the colon, proved radiologically. Of the cases of colonic disease or disorder 612 were cases of diverticulosis. 535 came in the general colitis group, including mucobranous, spastic, and catarrhal or mucous colitis and enterocolitis, and there were fifty-one cases of ulcerative colitis and colitis gravis, thirty-three of dysentery, seventeen of post dysenteric colitis and forty-four of other parasitic diseases. In this series there were sixty-four cases of growth, excluding growths in the rectum. The average age of the patients who had colitis or colonic delay was in the middle or late forties whereas the average age of those who had diverticulosis was 58, of those who had diverticulitis 62, and of those who had cancer it was also 62. The sex incidence was of some interest in colitis there were three women to one man, in constipation the numbers were equal—a rather surprising result—in diverticulosis there were two men to one woman, in diverticulitis nine men to one woman, and in growths three men to one woman.

In the diagnosis of diseases of the colon—which was not his subject on that occasion—he mentioned that although they had all been drilled by their teachers always to examine the anus and rectum cases still came forward in which the diagnosis had been missed owing to the neglect of such examination. The habit had grown up of making the diagnosis from the barium enema alone, but there were some things the barium enema did not show. It did not reveal the rate of passage, it did not indicate segmentation or spasm of the colon anything like so well as the meal, nor did it show well the faecal concretions which occurred in diverticula and were the beginning of diverticulitis.

Constipation

Flatulence was often mentioned in medical reports and documents without definition. It might mean that the patient was bringing up wind from the stomach or trying to, or passing wind from the bowel, or wanting to or that he was distended, or felt that he was distended without being so, or that he had gurglings with or without any of these things. A good many people were said to swallow air when they had some irritation in the stomach or some other organ. It should be found out to what the flatulence was due. With regard to distension of the abdomen, a comparatively slight distension of the small intestine produced an appreciable effect, whereas distension of the large intestine was well borne. In a series of 1,000 cases with a complaint of constipation no delay was shown radiologically in 10 per cent. The sexes were about equal though one would have expected women to be in the majority. It might be that women took aperients a great deal more than men. In 1,000 cases with radiological delay the delay was in the sigmoid and/or rectum in nearly half, and in the other half in the colon. Nearly a quarter of the 1,000 patients were unaware that there was any delay, they had come for investigation for other complaints and among these nine out of ten had no disorder referable to the colon. A reasonable delay was part of the colon—

function and remembering this, it might be well to revise some extreme views held in regard to constipation. It should be borne in mind that a purge emptied two or three days' faeces, so that it was hardly reasonable to give it at more frequent intervals. He believed that the caecum was not a "cesspool" as a rule though it might be made one by art, that a moderate constipation was not harmful, and that frequent purges were undesirable, causing loss of vigour of the intestine.

Mucous colitis was much less common in his experience than formerly. In the course of the last generation teaching as to purgatives had done something to decrease its incidence.

In 142 out of over 5,000 x-ray examinations a redundant sigmoid was observed. Was this congenital or in part congenital, or was it acquired? It was known from x-ray observation that when the bowel relaxed it became longer as well as wider. Supposing it did not contract again and that happened time after time one would expect to get these loops enlarging. He found a redundant sigmoid twice as common among people over 50 as among people under 30, taking equal numbers in each group. It would be interesting to elicit opinions as to the value of excision and sympathectomy. The latter was a valuable measure, no doubt, in Hirschsprung's disease. The bowel did not come down to the normal size, but it acquired a better tone.

Ulcerative Colitis

In ulcerative colitis whatever was done a proportion of patients—16 per cent in his series—died. Among the advances that had been made in his time was first of all, an increase in the diet. People with ulcerative colitis were now given any bland food that they could take. He had seen a patient get well on minced meat. He believed that gentle douching, not more often than on alternate days was a great help. It was important to deal with anal and rectal lesions. In his series of rather more than fifty patients up to about a year ago, when he published a paper on the subject, there had been five cases with entamoeba. Had a serum been found useful? Generally speaking bacteriological methods had been disappointing but some surgeons still reported good results. In this country the antidyenteric serum used was mostly Shiga, quite a sound one because it did contain the antitoxic body, but if the patient had not had Shiga dysentery and a Shiga serum was being given, that was non-specific protein therapy. Nevertheless some of the recoveries with serum had been in very ill patients. Antidiplococcal vaccines and sera had also been widely used. Sometimes after the fair hopes attending new methods of treatment had been dashed, there was an over-reaction. He was talking recently to an American physician, who said he had abandoned all treatment except rest, feeding and symptomatic medicines. That was going too far. Certainly as regards douching he believed it helped, and not only during the active stage, he had seen recurrence take place when it had been omitted, even during convalescence. He laid particular stress upon after treatment. It was a decisive factor in the large number of patients who recurred.

Ulcerative colitis however treated was a recurring disease and many lives were lost because that was not recognized. He had seen recurrence consequent upon overwork, emotional stress, the drinking of beer, the common cold, and pregnancy.

Diverticulosis and Diverticulitis

The incidence of these conditions was 10 or 11 per cent. He had suggested that the name diverticulosis be used when the pouches were present but had not caused inflammation of the wall of the bowel and that the term "diverticulitis" be reserved for cases in which there was induration or inflammation of the bowel wall. This definition had been accepted but it should be emphasized because it was of clinical importance. The incidence of diverticulitis in his series was 120 cases out of 612 people observed with diver-

ticulosis, in other words, 20 per cent went on to diverticulitis. Serial instantaneous photographs of diverticula contracting showed that the function of emptying was important. The muscular wall of the bowel must be kept in a good state if diverticula were to be kept healthy. A form of diverticulitis which he had described was that of swollen mucosal folds. This was most likely to cause acute obstruction.

The treatment of diverticulitis he recommended consisted of giving paraffin, administering a douche at periods of from two to seven days, varying according to the condition, avoiding rich food and too much alcohol, and generally living a hygienic life. When a man was subject to any complaint, if he abandoned discretion or was tired or worried, the complaint raised its head, and that was particularly true of diverticulitis. Purgatives should be avoided unless they were necessary.

Carcinoma of the Colon

Sir Edmund Spriggs then referred to the series of cases of growth of the colon analysed by Dr S W Patterson and himself and reported in the *Journal* of April 24 (p 882). In 64 cases, excluding growths of the rectum the youngest patient was 39 and the oldest 92, and the usual age period was between 50 and 70. Half of the growths were in the sigmoid. Diverticulitis combined with growth was seen in six cases only. Treatment depended on early recognition. In this series the length of history varied from one week to three years. There were fifty-five patients from whom a good history was obtainable, and among these the average time from the occurrence of the first symptom to the recognition of cancer of the colon was eleven months. Excision of cancer was nowhere more successful than in the colon if done early, and if it was generally recognized that there was on the average a gap of eleven months between the first symptom and the recognition of the true condition a step would be taken towards successful treatment. Of these sixty-four cases thirty-six had what might be called a bowel onset—either constipation or a colitic condition with irregularity, seventeen had pain as the first symptom usually referable to the growth or to the bowel above it, and eleven had what had been called a dyspeptic onset. Of course there was very generally dyspepsia in the late stages of obstruction, but he was now speaking of the very first symptom. Rectal bleeding was the first symptom noted in eleven cases, in seven there was neither blood nor pus detectable in the faeces. Thirty-eight of these cases underwent operation. Excision was carried out in thirteen cases, and in eight it was successful—two were alive after ten years. In excising carcinoma of the colon one should not be afraid of a big lump or a great dilatation of the bowel behind. The nature of the growth and the presence of secondaries were of more importance than the size or the degree of obstruction, provided the patient was not too ill.

One thing that emerged from the whole of this study was the amount of human suffering that might be avoided by fairly early adequate examination in doubtful cases. Finally, Sir Edmund touched upon the need for considering the mind of the patient as well as the body in this group of diseases.

Discussion

Mr J P LOCKHART-MUMMERY referred to the confusion between chronic dysentery and ulcerative colitis. Some times cases apparently of ulcerative colitis were treated indefinitely whereas if one could be sure they were cases of chronic dysentery they could be cleared up in a very short time. In a bad case of ulcerative colitis where there was a possibility of chronic dysentery he instituted emetine treatment. If it did not do good it did not do much harm. Ulcerative colitis was a disease which was continually recurring. He believed there was some hereditary disability. In certain people the colon was less resistant than in

others. In three cases he had treated both father and son or daughter for exactly the same condition, which was rather suggestive of a hereditary factor. In one case a septic tooth was the cause of recurrence. On the question of the treatment of chronic constipation by resection of the colon or by sympathectomy his own experience of sympathectomy was that while satisfactory in its way it was not permanent and recurrence took place. The same was also true of the megacolon cases. But there was a very great difference from the point of view of risk between resection of the colon and sympathectomy. It had to be a very bad case if colectomy was justifiable, but there were cases where it was.

Mr ERIC CROOK said that in mental patients the incidence of volvulus appeared to be much higher than in other patients. In surgery at a mental hospital volvulus was found to be a far more common emergency than appendicitis. He did not know whether this was due to any relative rarity of appendicitis among mental patients or was attributable to a back-pressure effect. Sir ROBERT ARMSTRONG-JONES said that his experience at Claybury over many years was that volvulus was exceedingly rare, appendicitis was equally rare. Dr G. VILVANDRÉ said that the older he got the more difficult he found it to diagnose carcinoma of the bowel from x-ray appearances and the more reliance he placed on the sigmoidoscope. Mr R. S. CORBETT referred to the prevalence of intussusception in connexion with growths in the colon. Mr E. T. C. MILLIGAN asked under what conditions the opener had come across flatulence in the small intestine, which was a very common complaint among many patients. Where did the air come from?

Mr GORDON TAYLOR associated himself with what had been said about the relatively slight value of sympathectomy in cases of chronic constipation. The almost miraculous results of sympathectomy in Hirschsprung's disease in children were well known, but when it came to chronic constipation in adults or even adolescents his experience of sympathectomy was that it had at most a temporary effect, and in every case he had had subsequently to perform a resection. He was not quite prepared to accept Mr Lockhart-Mummery's view as to the excessive risks of colectomy. He had been interested in the relative infrequency of the combination of diverticulitis and cancer. Did a patient ever get a perforated diverticulitis twice? He had operated in a large number of cases of perforation of diverticula of the colon but he had never known a second perforation in the same patient.

Sir EDMUND SPRIGGS replied that he too had not seen a patient with a second perforation of a diverticulum. He agreed with Dr Vilvandr  that the recto sigmoid junction was a part which in many patients could not be well seen radiologically, however the patient was rotated but it could be seen with the sigmoidoscope. With regard to a hereditary or familial factor in ulcerative colitis he had only come across one case out of the fifty in his series in which this presented but in that case four members of one family were affected.

E. Junghans (*Med. Welt* April 17, 1937 p. 530) draws attention to the dangers of the indiscriminate use of extracts of the posterior lobe of the pituitary during parturition. He reports four cases of rupture of the uterus following the administration of pituitary extracts and recommends the following rules. The intravenous injection of pituitary extracts during the stage of dilatation and expulsion is contraindicated. During the stage of dilatation only small doses of stimulating drugs are permissible. In cases of disproportion between head and pelvis and in the presence of weak uterine contractions pituitary extracts are permissible only when a thorough vaginal examination has shown that spontaneous delivery is possible. The dose to be injected must not exceed three Voegelin units.

ENGLAND AND WALES

Birmingham United Hospital

The Birmingham United Hospital, consisting of the General Hospital in Steelhouse Lane and the Queen's Hospital in Bath Row, has issued its second annual report covering the year 1936. Finance is dealt with as relating to the one organization, but each hospital retains its own list of subscriptions and donations, which in the case of the General Hospital amounts to over £10,000 and in the case of Queen's Hospital to little less. Apparently the arrangement reached in 1934 to unite these hospitals has not diminished the interest of their friends in one or other institution. On the united working there is a small surplus of £313, comparing with a deficit of £625 the previous year. Great assistance has been afforded by the Birmingham Hospital Contributory Association, whereby nearly £77,000 was received by the hospital during 1936, an increase of £3,000 on the previous figure. The hospital has again been fortunate in the receipt of free legacies amounting to £47,286, which has been placed to a separate legacy account. A table is given showing the expenditure per patient at each hospital during the last six years. The cost per in-patient at the General Hospital has gone down from £8 16s 1d in 1931 to £8 0s 10d in 1936, and at Queen's from £7 15s 11d to £7 3s 1d. The cost per out-patient has remained fairly constant at the General Hospital at 6s 7d, and at Queen's it is now at that same figure, to which it has progressively risen from 4s 3d in 1931. It is mentioned that Lord Austin, the chairman of governors, undertook to defray the cost of one gramme of radium for use in a bomb, and this has now been installed at the General Hospital. The number of in-patients at the General Hospital during the year was 8,562, and at Queen's 6,856. A neurological department has been inaugurated at the former hospital. It is expected that the opening of the new hospital at the Centre will take place in 1938.

International Union Against Cancer

The Minister of Health, Sir Kingsley Wood, presiding on May 22 at a dinner given by His Majesty's Government at Lancaster House, London, S.W. to the International Union against Cancer, said the fight against disease knew no political barriers and no national frontiers. Cancer research was proceeding unceasingly. Devoted workers in almost every country in the world to day were working steadily and quietly in the attack on cancer which was still one of the most deadly enemies of the human race. This work went into the common stock for the welfare not of one country nor of one continent but of humanity. Although the cure of cancer had not been discovered, nevertheless if the disease was caught in its early stages—and treated by surgery, by deep x-rays, or by radium—it had shown a high recovery rate. It was simply untrue, as too many people thought, that a diagnosis of cancer was necessarily a death sentence. In Great Britain for instance, it was true that over 60,000 people died every year from cancer. When however the increased longevity of the population and the more accurate diagnosis of the disease were taken into account, it was probably fallacious to assume that these figures connoted a greater prevalence of whatever factors were concerned in its causation. So far as treatment was concerned the position generally was more hopeful than at any time and thousands of people were being cured to-day. This fact could not be too widely known, for perhaps an even more deadly enemy than cancer was the nameless fear which caused a man or woman to destroy

until it was already too late. M. Justin Godart, formerly Minister of Health in France, who said in reply that he shared the optimism of Sir Kingsley Wood, emphasized that means and methods had been worked out which had brought relief to thousands of sufferers. The most hopeful outlook lay in the fact that people, more and more, were losing the terror which the name of the dreaded sickness had been causing for centuries, and were, therefore, seeking early treatment. M. Godart, in the name of all nations represented on the Union, paid tribute to the work done in England since the end of the eighteenth century.

Maternity and Child Welfare Conference

The full programme has now been issued for the seventh English speaking Conference of Maternity and Child Welfare, which (as announced in the *Journal* of February 27 p. 468) will be held in the Great Hall of British Medical Association House, Tavistock Square, W.C., on Tuesday, Wednesday, and Thursday, June 1, 2, and 3, under the presidency of the Minister of Health, Sir Kingsley Wood. Discussions will take place on 'The Promotion of Maternity and Child Welfare in Backward and Rural Areas' (chairman, Sir George Sill), 'Progressive Legislation in Connexion with Maternity and Child Welfare', 'The Education of Parents in the Care of their Children' (chairman, Dame Enid Lyons, wife of the Prime Minister of Australia), 'Nutritional Problems in Relation to Mother and Child' (chairman, Dr R. E. Wodehouse, Deputy Minister of the Department of Pensions and National Health, Canada), 'The Future of Preventive Psychology in Relation to Parent and Child', and 'Preventive Work for Cripples and Invalid Children'. The Minister of Health of Tasmania, the Hon. G. F. Gaha, is also attending the conference. There will be a reception by the Minister of Health on behalf of the British Government at Lancaster House at 9 p.m. on June 1, and a reception at the College of Nursing on June 2 at 8 p.m. The Child Welfare Travelling Exhibition of the National Council for Maternity and Child Welfare will be displayed at Woburn House, Upper Woburn Place, W.C. (opposite B.M.A. House) throughout the three days. Arrangements have been made for tours and visits to institutions all of which start from B.M.A. House. Particulars of the conference may be obtained from the honorary secretary, Miss J. Halford, Carnegie House, 117, Piccadilly, W.1.

SCOTLAND

Lord High Commissioner and Hospitals

Lord Kinnaird, as Lord High Commissioner to the annual Assembly of the Church of Scotland and Lady Kinnaird, following the usual custom, paid a round of visits last week to the hospitals in Edinburgh. At the Royal Infirmary on May 18 Lord Kinnaird presented the prizes gained by nurses in examinations, and visited two surgical wards and one medical ward. Lady Kinnaird also paid a visit to the Scottish Branch of the Queen's Institute of District Nursing where she was received by Lady Nairn who reminded her that this was the jubilee year of the Queen's Institute the Institute having been founded in 1887 following the decision of Queen Victoria that the money presented to her then in memory of her fifty years reign should be spent in providing nurses for the sick poor in their own homes. The first of these nurses had been pioneers of a wonderful movement which had greatly increased so that in Scotland there were now over 1000 of these nurses. On May 19 at the Deaconess Hospital of the Church of Scotland the Rev. Dr. Fiddes in an address of welcome said that this was the first visit of the King's representative since the hospital had been reconstructed and reopened last year by the present King and Queen as Duke and Duchess of

York. The reconstruction had cost £42,000, and this had been subscribed with the exception of some £3,500. The Royal Maternity and Simpson Memorial Hospital was visited by Lady Kinnaird, where she saw six infants that had been born on the forenoon of the day when the visit was paid. On May 21 both Lord and Lady Kinnaird visited the Edinburgh Foot Clinic. Sir John Fraser, who presided, said that this clinic was in some respects a unique institution. It had a record of some 21,000 cases annually, all of them presenting disabilities of the feet which caused great distress to the sufferer and were sometimes so crippling as to make walking impossible. Miss Gertrude Herzfeld said she had been interested in the clinic since it began with four treatment chairs; now there were forty chairs. The clinic had taken thirteen years to develop, and the work now being done among children was of great importance, because it was not only preventive but educational. This school turned out a large number of competent chiropodists, and it was to be hoped that some day it might be endowed. Lord Kinnaird said that the public ought to appreciate this work, and should not allow such a clinic to go short of funds.

Presentation to Portobello Doctor

Dr. John H. Balfour, who has retired from practice in Portobello, Edinburgh, after fifty-five years was presented recently with a wallet of money on behalf of a large number of patients and citizens. Councillor James Edward, in making the presentation said that Dr. Balfour began his professional career in Portobello at the age of 21 as assistant to his father. He had not only been one of the best known practitioners in the city of Edinburgh, but had thrown himself with energy into many forms of work for the benefit of the community. For fifty years he had rendered valuable service to the Portobello Destitute and Sick Society. Dr. Balfour, in returning thanks, said that he had always considered his patients as his friends, an attitude which he thought every medical man ought to adopt with the object not only of benefiting the health of the patients but of helping them in every way possible.

Royal Victoria Hospital Tuberculosis Trust

The annual report of the Royal Victoria Hospital Tuberculosis Trust by Sir Robert W. Philip, president of the Trust, for the year to June 20, 1936, states that deaths from tuberculosis in Scotland now number only about one quarter of what they were fifty years ago. It is pointed out that beyond the immense saving of life such figures afford convincing evidence of the improvement that has taken place in methods of detection and in the advances made in prevention and treatment. Nevertheless the death rate in the age group of children under 5 years was 299 per 100,000, a figure which affords testimony to the fact that infection with tuberculosis is to be expected in infancy and childhood. The seeds of tuberculosis as manifested in adolescent and early adult life may therefore be regarded as having been sown in infancy. The disease may kill the patient at the beginning through the virulence of infection and the low resistance offered, or it may merely cripple, or may remain latent until some time when the individual's resistance falls. Attention is directed to the value of recognizing infection at the earliest possible moment by the tuberculin test. Thereafter ideal physiological conditions of existence should be provided for the children and for this purpose the Southfield Sanatorium Colony of the Trust has been found most suitable. The research laboratory of the Trust has undertaken a considerable amount of work. Dr. Christopher Clayton has investigated the seasonal variation in the manifestations of tuberculosis and has come to the conclusion that these are referable chiefly to two factors: fluctuation in the resistance of the individual and variations in the virulence of the infecting organism, the former being the more important. Dr. Iain Macdonald has con-

ducted observations to ascertain if the healing of tuberculous lesions by means of calcium might be accelerated by the addition of tuberculin, vitamin D, or cholesterol in varying combination. Cases treated with tuberculin have been found to show a definitely increased deposition of calcium. Dr J. M. Matheson, from the clinical aspect, has made a study of the circulatory and respiratory functions in tuberculosis, paying particular attention to arterial pressure and respiratory capacity. At the sanatorium an open-air school has been successfully conducted, and it has been observed that under the conditions of this school the child's mental processes are amazingly quickened. Much attention has been paid by the Trust to education in the prevention of tuberculosis, short courses of intensive training in tuberculosis work have been provided for nurses, and leaflets, cards, and posters have been distributed among the public. The tubercle-free dairy herd of cows at Gracemount farm in the neighbourhood of the sanatorium now numbers 111 cows. It is further noted that the number of cows in attested herds throughout Scotland in July, 1936, was 11,826, approximately five times as many as in July, 1935. The financial statement of the Trust shows that the ordinary income for the year was £4,802, while the expenditure was £5,922. The invested funds amounted to £36,036.

FRANCE

[FROM OUR CORRESPONDENT IN PARIS]

The Reorganization of the Public Health Service

Monsieur Henri Sellier, Minister of Public Health, continues to issue notes and memoranda on the reorganization of the public health service. It will be remembered that the Decree of October 30, 1936, provided for the appointment in each department of an inspector of hygiene responsible to the Minister of Public Health. In April of this year the Ministry of Public Health issued particulars concerning the duties of this medical officer of health. He is to act as the secretary of the Departmental Hygiene Council and of those departmental bodies called into being to assure the proper co-ordination of health activities. The medical officers on the staff of an inspector of hygiene must be French doctors of medicine holding a university diploma of hygiene and a certificate showing that they have spent three months in the study of departmental inspection or in the municipal health service of a town with at least 100,000 inhabitants. The appointment of such officers is to be by examination, and the board of examiners is to be composed of medical experts in public health. The directors of public health services are to be selected by this board instead of being nominated as heretofore by the municipal authorities. The age limit is 60 years, and private practice is not allowed except in towns with less than 50,000 inhabitants. What is perhaps the most striking feature of this reorganization is the emphasis laid on technical skill and experience throughout the new hierarchy and the corresponding weakening of lay and local bonds. Monsieur Sellier is evidently bent on gradually eliminating the layman's usurpation of functions which can properly be discharged only by fully qualified medical officers of health.

"Le Sou Médical"

The medical defence union "Le Sou Médical," now some forty years old, is a most prosperous body with nearly 8,000 members and a big financial reserve. Members whose clinical and therapeutic activities bring them into the law courts are guaranteed a support of 100,000 francs which is raised to 500,000 for those who are also subscribers to the weekly journal, *Concours Medical*. In 1936 the letters received by this organiza-

tion numbered more than 11,000, and 537 new cases were handled. In as many as 151 of these cases the trouble concerned the payment of fees. In twenty-one first-aid on the highways had led to differences of opinion between doctor and patient. There were also fifty-nine cases concerned with occupational accidents, nine with slander, nine with difficulties over rent, eight with difficulties between colleagues and as many as eighty-four with the tax collector. In the same year 667 cases were wound up, only sixty-four, or 10 per cent, being lost. In all the other legal cases "Le Sou Médical" scored a victory for its members. Its staff includes six legal experts. All this for 100 francs a year, with the *Concours Medical* thrown in for an additional 60 francs.

The Tercentenary of Descartes

It was in 1637 that René Descartes published his famous *Discours de la Méthode* and some time this year an appropriate ceremony will presumably celebrate this event. At the end of his *Discours* Descartes asserted bluntly that his was the ambition to improve the art of healing, and he intimated that by pursuing a study of nature he might extract therefrom rules for the conduct of medicine more reliable than those then in force. He ventured on a description of the action of the heart and blood vessels, not a bad essay considering the date on which it was written. His advocacy of observation and experiment may not have been given place of honour in his scheme of reform, but it is remarkable that they were given any place at all. It was in 1649 that Descartes came to Stockholm on the invitation of Queen Christina of Sweden and he died there in 1650. His remains, minus the skull and a bone of the hand which had written the *Discours*, were taken to France in 1667, and now rest in Saint-Germain-des-Prés in Paris. But the retentive Swedes were long in parting with the skull, and it was not until 1878 that it was acquired by the French Museum of Natural History, where it now réside after having been bought for 37½ gold francs.

State Employees and Tuberculosis

Dr E. Rist has lately drawn attention to the injustices of the law of 1929 concerning sickness benefit for State employees who develop tuberculosis. According to Article 51 of this law the servant of the State may, on developing tuberculosis, take five years' leave of absence in which to recover, the first three years on full pay and the next two on half-pay. To repair the generosity of this gift the State has become most evigent in its health standards for applicants for the service. They have to be examined by a specialist, who must employ radiological as well as clinical means for discovering traces of tuberculosis. He has to testify to the absence of any tuberculous affection, so when he finds a radiological shadow in the lungs, however insignificant, he is involved in a conflict between clinical common sense and the letter of the law. Certain examiners whose logic has outrun their common sense have most unjustifiably wrecked the prospects of the persons examined. Dr Rist suggests, tongue in cheek, that the examination for State service should include a tuberculin skin test, the positive reaction of which would disqualify some 75 to 80 per cent of all the healthy applicants between the ages of 18 and 25 for State service. Dr Rist's serious remedy is to give highly qualified medical examiners more latitude and to let them pass into the service of the State a certain number of ex-tuberculous patients, even when their health records have been tarnished by artificial pneumothorax or sanatorium treatment. But such persons should be put on probation for a certain period during which the State should not be liable to give them tuberculosis benefits if they broke down from this disease. The mere fact of their being on such probation as well as being under close, skilled medical supervision should keep such persons in the narrow path of healthy living.

Correspondence

Memorial to Professor E H Kettle

SIR—By the death of Edgar Hartley Kettle in December last pathology, in this country, lost one of its most distinguished exponents, and all who knew him were deprived of a personal friend. We feel sure that those who were associated with him, as colleagues or students in his professional work, or in any other of the activities in which he took part, would desire that his memory should be perpetuated in some suitable form.

Kettle's devotion to his subject, and to all that concerned it, including particularly the interests of his students and younger colleagues, was evidenced throughout his professional career. As an original worker, as a director who stimulated the work of others, as a teacher as a senior member and treasurer of the Pathological Society, and as an active member of numerous committees he played a part that will not be forgotten. In each of the four University schools in which he directed the teaching of pathology—St Mary's, Welsh National School of Medicine, St Bartholomew's and the British Post-Graduate Medical School—he won the admiration and affection of his colleagues and his students. We feel that a fitting tribute to his memory would be the foundation of a Kettle Memorial Lectureship in Pathology, and that this lecture might appropriately be given annually, in each of these schools in turn.

An endowment fund is being collected for this purpose, and we are sure that his colleagues and friends, including many who though not pathologists, were associated with him in connexion with his pioneer work on silicosis or in other ways would wish to be given the opportunity of contributing. It is suggested that individual contributions should not in most cases be more than two guineas and smaller sums will be welcomed.

Contributions should be sent to the Treasurer, Kettle Memorial Fund, British Post Graduate Medical School, Ducane Road, W12. Cheques should be drawn in favour of the 'Kettle Memorial Fund and crossed Barclay and Co.—We are etc.,

Prevention of Constipation

SIR—Correspondents in the *Journal* have recently urged the importance of establishing a bureau of geographical medicine. Such statements as "Chinese of the upper classes do not suffer from high blood pressure" would come under its investigations. Dr E. M. Dimock in his article on the prevention of constipation (*Journal* May 1 p 906) states that constipation is practically unknown among savage tribes. Dr Dimock's article contains much sage medicine and also much sage psychology which is as he points out, of great importance in the treatment of constipation. I am not criticizing his article, but as

a rider to it may I point out certain lessons which can be deduced from the sentence quoted?

Is it correct that savage tribes do not suffer from constipation? Messrs Parkc Davis and Co first discovered cascara sagrada by hearing of a drug in use for constipation among the North American Indians. But it may be reasonably correct to say that in warmer climates savage tribes do not often come to medical officers for treatment for constipation. Is it possible that they find that much of what we call constipation can conveniently be left alone? The lay members of a civilized population label as constipation any habit of the bowels which does not involve at least one daily motion. Some healthy persons have two motions daily. In general they tend to be proud of this cycle. It appears to give them a sense of superiority, and few would think of taking medicine to reduce this frequency. But some individuals have their maximum of health with four or five motions a week and no aperients.

Such persons in war time would largely be classified as B or possibly C, but in civilian life they are efficient members of the State. As such individuals pass into adult life they begin to flog their alimentary tract with aperients to attain the intestinal activity which they believe will in itself give them perfect health. They are at their worst when they take an aperient which fails to act and at their next worst when they force their bowels into two or three loose motions daily. They are at their best with no aperients even if they pass only four or five motions a week. But the psychological aspect must be borne in mind and the inferiority complex associated with their so-called constipation must be allayed.

Bran meets both the necessary conditions. It dispenses with aperients and soothes the mental anxiety. Personally I prefer physical exercises for most cases, and there are also other varieties of treatment which can be applied to individual conditions but the principle that a reasonable degree of 'constipation' gives such persons the maximum comfort and health is the same.

I have found on several occasions that when these persons have attained a satisfactory routine and are rejoicing in the sensation of good health they are under the impression that the bowels are being opened daily whereas a careful record shows about five motions a week. They can usually be persuaded to leave well alone—I am, etc.

London W 1 May 20

H LETHBRIDGE TIDY

SIR—No one who has been in active general practice for as many years as I have can fail to have come to certain conclusions about constipation: its cause, prevention, and rational treatment. My own experience has led me to agree much more wholeheartedly with the old-fashioned doctors who regarded the prompt evacuation of the bowels as nine times out of ten one of the first therapeutic measures to be taken in treating illness of almost every kind than with the apostles of the newer school who pooch pooch constipation either as entirely normal and desirable or as of no particular importance.

Dr Dimock's article in your issue of May 1 (p 906) interested me and to a large extent my experience confirms his conclusions. But some of his remarks seem to me to betray a good deal either of prejudice or of unawareness. Dr Dimock says that as constipation is practically unknown among savage tribes it would appear that a method is required which will overcome the disadvantages of our civilized diets and sedentary occupations. We can all overcome the disadvantages of our civilized diets to some extent by including in them 2

much larger proportion of uncooked salad, fresh fruits, and 'processed' bran in our daily menu. When we have done that, and have established the practice of drinking three or four pints of water daily between our meals, we shall have done nearly all we can in the matter of diet. Dr Robert Hutchison, in his *Elements of Medical Treatment* wrote

"In spite of the general belief not very much can be done by diet in the treatment of constipation—at least in cases bad enough to come to a doctor at all. In the great majority of cases drugs cannot be dispensed with, and the patient's mind should be disabused of the idea that there is any particular harm in taking a regular aperient provided it is of the right kind."

What is the right kind of aperient? As a result of my own experience I have come to the conclusion that nearly every aperient in the *Pharmacopoeia* has its appropriate occasion, but that in the overwhelming majority of cases of mild constipation a laxative that is not absorbed, that stimulates peristalsis by increasing the internal tension of the alimentary canal by mere bulk and not by chemically irritating the sensitive nerve endings of the intestines is to be preferred. This is particularly important when we are dealing not with acute but with chronic constipation, however mild. That is where Dr Dimock seems to me sound, and he specially recommends for the prevention, but not for the cure, of constipation bran, because 'by virtue of its power to retain moisture it is a mechanical laxative'.

That brings me to the sentence in Dr Dimock's article that struck me as based on inadequate reflection or knowledge. Under the term purgative I include aperients, salines, and all laxatives that are not purely mechanical. Not one of these medicines is physiological in action. In what essential I would ask, does the aperient action of a saline such as a seditiz powder or a dose of fruit salts differ from that of those substances which Dr Dimock rightly regards as desirable, because they act merely 'by virtue of their power to retain moisture'? Fibre agar, psyllium seeds, bassorin, and certain other vegetable products absorb and retain fluid as a colloidal property, salines such as those mentioned achieve precisely the same result through the physical process or principle known as osmosis. These salines act as painless aperients merely by their power of retaining within the intestine a large part of the fluid taken with or after them. They do not irritate the lining membrane of the intestine, and they pass from the body without any direct chemical interaction at all. They have the further merit of never causing obstruction, as bran occasionally—though rarely—does. This is acknowledged by Dr Dimock, who also admits that fibre is useless for the relief of established constipation.

When some artificial encouragement to bowel action seems called for it seems to me that we should in the first place endeavour to bring about the desired result by prescribing an increased amount of active outdoor exercise, a greatly increased consumption of water, and a larger daily intake of green vegetables, salads and fruit. These measures may be supplemented—usually for a time they must be supplemented—by the regular taking with abundance of fluid of one or other of those substances which have the capacity of retaining within the body a sufficiency of that fluid to form a colonic bolus bulky, soft loose and non-irritant. Among such substances the so-called fruit salines—that is, the tartrates and citrates—stand out as among the most agreeable to the palate and the least disturbing to gastric digestion—I am, etc.,

London E 1, May 19

HARRY ROBERTS

SIR,—With reference to the suggestion that bran may be given in cases of colitis (*Journal* May 8, p 996) I should like, from personal experience, to utter a warning against the indiscriminate administration of anything that is at all likely to cause further irritation to the bowel in this condition, particularly in the more acute types. Whatever the primary cause of "non specific colitis" the bowel is undoubtedly very much inflamed, and surely the first rule of treatment in any inflammatory condition is rest as far as possible. Most certainly nothing further should be given, either by the mouth or bowel, that is likely further to disturb the bowel. The futility and harm done by bowel wash outs is being recognized, and this form of treatment is gradually being discarded, a tendency probably accelerated by the refusal of patients to accept the associated pain and distress. It is equally possible and very much easier to aggravate colitis by irritants given orally. When what almost amounts to a policy of despair has been reached in the treatment of this difficult condition, and little headway seems to be made on the "no residue" diet, the opposite extreme—a "roughage" diet, has been advocated, with some idea of producing a more formed motion. Absorbents like isogel have also been suggested for the same purpose. The effects have to be experienced to be realized.

In this connexion I should like to add a word of caution on the administration of iron for anaemia in colitis. It does not appear to be as widely recognized as it should how acutely irritative to the mucous membrane of the lower bowel iron can be. When the mass dosage of iron for the treatment of anaemia was first introduced I was struck by the frequency of patients' complaints of resultant looseness of the bowels. The probability of this occurring in cases of colitis has been recognized by some enthusiastic iron prescribers, and they agree that there may be a preliminary aggravation of the condition before any improvement manifests itself. My experience suggests that if the administration of the iron is persisted in, with evidence of susceptibility, the primary aggravation may so far develop that the secondary beneficial stage may never be reached—I am, etc.,

London, May 17

"M B"

Reform of Medical Curriculum

SIR—I was greatly interested in the debate in Edinburgh on the reform of the medical curriculum as reported in the *Journal* of May 15 (p 1040), and I should like to make some comments which I hope will be helpful. The resolutions of the General Medical Council, to come into force in 1938, were, I gather, generally received with favour, but Sir Francis Fremantle criticized the tardy acceptance by the GMC of reforms which had been suggested as long ago as 1922. Now it ought to be clear to those with a practical interest in medical education that it is not incumbent on medical schools to wait for a lead from the GMC before undertaking reforms in the curriculum. The function of the GMC in this respect is rather to consolidate into resolutions those reforms which medical schools have already instituted, in the same way that Parliament passes laws when public opinion has been sufficiently educated to demand them. The GMC resolutions ought to be necessary merely to coerce the laggards and not to lead a reform, were it otherwise medical schools would be in danger of losing their individuality. Thus Sir Francis Fremantle's indictment of the GMC should really be an indictment of all medical schools who failed to appreciate the importance of the 1922 suggestions which have inspired the recent resolutions of the

G M C It ought to be more widely known, I think, that the reforms outlined in 1922 and given publicity in the medical press at that time were put forward by my predecessor, Professor J B Leathes, F.R.S., and almost immediately carried into effect in the Sheffield Medical School, with the loyal co-operation of all members of the staff. Further improvements were introduced in 1930, when the curriculum was lengthened by six months. The result of this far-seeing enlightened policy is that the curriculum of the Sheffield Medical School needs no adjustment to satisfy the new requirements of the G M C. It is true we shall need additional accommodation at our teaching hospitals so that students may spend a whole month in residence, but we have had for many years facilities for students living in hospital for shorter periods.

It is gratifying to gather from your report and from the *Edinburgh University Magazine* of April 27 that Edinburgh is stimulating herself to become a pioneer in reform of the medical curriculum but I hope you will appreciate how the thought passed through my mind—quite irrelevantly, I suppose—of the pioneer Vikings smiling indulgently in Valhalla at the 'pioneer' claims of discoverers of America in subsequent centuries—I am, etc,

The Maternal Mortality Report

SIR—Dr John J Buchan's comments (*Journal* May 22, p 1090) would be more useful if they were more accurate. In the first place he has confused the recommendation of the Ministry of Health Report, that

'the local supervising authority in consultation with the local medical profession should in future be empowered to take steps to ensure that the best local obstetrical skill is made available in all cases in which midwives are required under the Rules of the Central Midwives Board to call in a doctor' with the proposal in which it is stated that the Ministry of Health and the Central Midwives Board have under consideration "that a midwife should be allowed to call to her assistance such practitioners only as are selected by the local authority for this purpose."

In the second place Dr Buchan shows woeful ignorance of national health insurance. His analogy disappears when it is realized that the "panel" is open to every doctor who wishes to have his name placed upon it. Nor is it correct that doctors on the panel are paid for their services to insured persons when sick. Has Dr Buchan, in the seclusion of his town hall, never heard of the capitation fee? We are all agreed that the best local obstetrical skill should be made available. Some would seek to do this by restricting all maternity work to obstetrical specialists; others of whom Dr Buchan is apparently one prefer semi-specialists. Well Sir do the results to date of these two methods suggest that either of them is the best? Have ante-natal clinics staffed by whole-time medical officers been so brilliantly successful? If they have then what is all the fuss about? Is the hospital the domain *par excellence* of the specialists the safest place for a normal confinement?

On the other hand the policy of the British Medical Association is to make available to every pregnant woman the services of her own doctor—on the sole condition that he is willing to offer them—backed up when necessary by the help of a consultant. This is the method which works in other fields of medical practice which have not excited the same criticism as maternity work. It is not customary for every cold in the nose to be treated by a rhinologist.

Moreover, the Association policy does not overlook the cardinal fact that a woman, even though her uterus be pregnant is a human being only to be thoroughly understood by long acquaintance, and not merely by measurements of her pelvic diameters and blood pressure. Are women who have been literally terrified by their treatment at ante-natal centres, as I have seen them, in the best condition to undergo labour? Some of us see patients others read reports about them!

A further point in favour of the Association's policy is that it looks to the future. In the past circumstances have militated against the midwife in private practice sending for a doctor unless a serious emergency has arisen. A midwife who often summoned a doctor for apparently minor conditions would have incurred, most unjustly, a reputation for incompetence. In future under the guidance of the local authority, the midwife will be encouraged to send for the doctor at the first indication of trouble. He will therefore have to deal with a larger number of less serious conditions, and in his turn will be encouraged to call in a consultant whenever necessary. I am aware of the criticisms levelled at general practitioner midwifery, but these have been dealt with so ably by Dr H A Nathan (*Supplement* May 15, p 297) that I will not repeat his words. I notice, however, that there has been no hurry amongst medical officers of health to reply to Dr Nathan's letter. Is it because they have no reply available?

Finally, Sir, the Association's proposals envisage the participation in maternity work of a much larger number of doctors than the other schemes. We believe that this will give a better service, but admittedly the greater the numbers of doctors the greater the difficulties of control. Do medical officers of health want the best obstetric service or the one which they can most easily control?—I am, etc,

London, S W 18, May 24

F GRAY

Maternity Services

SIR—From a study of the maternal mortality report it would seem that our three principal defects are (a) insufficient attention is given to ante-natal care, (b) forceps delivery is too frequent, and (c) midwifery is carried out in unsuitable homes.

(a) Attention is called to a large number of cases in which ante-natal care was deficient, and there are various causes for this. In many areas a maternity officer is appointed who sees midwives cases before they go into labour, but this officer takes no responsibility for the actual confinement and when anything goes wrong the patient's own doctor is called in. He has had no opportunity of seeing the patient beforehand. He has had no chance of saying whether he will accept responsibility for the confinement in the existing surroundings and circumstances, and yet though working at the gravest disadvantage he must obtain satisfactory results. If ante-natal work is to be successful one practitioner should be responsible for each patient before, during and after her confinement. The situation and construction of the ante-natal clinics and the days of attendance require consideration because some women very much resent the long queues and the lack of privacy which might be avoided. The report notes that the patient's personal circumstances do not always receive sufficient attention. This is true and is worthy of further consideration.

(b) Forceps delivery was unsuccessful in 19.3 per cent of those patients who died after instrumental intervention. The time has surely come when failed forceps cases should be a thing of the past. The most frequent cause of failed forceps is premature attempts at delivery due usually to the insistence of the patient that she shall be relieved of her pain. Therefore if we are going to have satisfactory maternity services more attention must be given to the organiza-

tion required to enable all women to be relieved of their pain by means of gas and air analgesia

(c) We read that the reduction in the group of deaths following an abnormal labour will be effected only when general practitioners realize that they must not except in cases of emergency, attempt in the patient's home difficult obstetric operations. "This is a very excellent recommendation, but how is it to be carried out? As long as women are allowed to have babies in unsuitable homes we shall have obstetric operations undertaken in unsuitable surroundings. We should realize that the small house—occupied so often by two families—is not a suitable place in which to conduct a confinement

In order to enable us to work out the details of a national maternity service it would be of the greatest possible value if in every county and in every great city a conference could be held of all those interested in midwifery so that a district or county scheme could be approved. From districts or county schemes a national service could then be built up.

Since the introduction of the National Health Insurance Act the demands made on the time of the general practitioner have been so great that as a general rule he is not able to give adequate time to midwifery, and, as this report suggests, only those practitioners who are actually interested in this branch of work should be required to undertake it. There is one more point which needs the attention of the Ministry of Health: the report says that where women are engaged in gainful occupations the maternal mortality tends to rise, and it is evident that women should not be required to work right up to the time of their confinement.

A Ministry of Health circular calls the attention of practitioners to the fact that under the National Health Insurance Regulations pregnancy does not constitute incapacity for work. It is surely high time that this ruling was altered, and that women should of right receive sickness benefit for two months before their confinement is due—I am, etc.,

New Barnet May 20

JOHN ELAM

The Average Size of Families

SIR—In connexion with your leading article of May 22 on Mr Rowntree's book, *The Human Needs of Labour* and your incidental references to the average size of families, the following contribution may perhaps be of some small interest.

In the year 1932 for my own personal interest I worked out the average size of the families, both parents being still alive, from which a consecutive series of 500 boy and girl provincial candidates for service in the Post Office had come. They were assembled from all parts of the country and Northern Ireland and, including only living children, the average worked out at 3.2. Of the 500 mothers concerned 251 were 45 years of age or over, 111 of them having had no children for ten or more years, and 17 of them no children for fifteen or more years—I am, etc.,

H H BASHFORD M.D., M.R.C.P.

General Post Office E.C.1 May 21

"Constructive Conscious Control"

SIR—In a review of Mr F. Matthias Alexander's book *Constructive Conscious Control of the Individual* which appeared in your columns on May 24, 1924, your reviewer wrote: "He [Alexander] would certainly appear to have something of value to communicate to the medical profession."

We the signatories to this letter are at one with your reviewer in this belief. As the medical men concerned we

have observed the beneficial changes in use and functioning which have been brought about by the employment of Alexander's technique in the patients we have sent to him for help—even in cases of so-called "chronic disease"—whilst those of us who have been his pupils have personally experienced equally beneficial results. We are convinced that Alexander is justified in contending that "an unsatisfactory manner of use, by interfering with general functioning, constitutes a predisposing cause of disorder and disease," and that diagnosis of a patient's troubles must remain incomplete unless the medical man when making the diagnosis takes into consideration the influence of use upon functioning.

Unfortunately those responsible for the selection of subjects to be studied by medical students have not yet investigated the new field of knowledge and experience which has been opened up through Alexander's work, otherwise we believe that ere now the training necessary for acquiring this knowledge would have been included in the medical curriculum. To this end we beg to urge that as soon as possible steps should be taken for an investigation of Alexander's work and technique, he on his side having given us an assurance that he is ready and willing to give us the benefit of his experience for the carrying out of any plan which those concerned may suggest, provided that in his opinion the plan is one that would make it possible for him to help us to the desired end.—We are, etc.,

What is Osteopathy?

SIR—Careful perusal of the minutes of evidence given before the Select Committee of the House of Lords appointed to consider the Registration of Osteopaths Bill demonstrates, I submit, that one of the principal reasons for the precipitate withdrawal of the Bill by those responsible for promoting it was the devastating exposure of the British School of Osteopathy. The committee found that

"the only existing establishment in this country for the education and examination of osteopaths was exposed, in the course of evidence before us, as being of negligible importance inefficient for its purpose and above all in thoroughly dishonest hands." But the promoters of the Bill had accepted that school as completely satisfactory, and this fact renders suspect the testimony to the character and value of the training given by the "six colleges approved by the American Osteopathic Association," which are declared to require a course for graduation as Doctor of Osteopathy of four years and nine months each.

It is common form for irregular practitioners of every complexion to parade what looks on paper a formidable curriculum of study. I have drawn attention in your pages to similar pretensions made by the herbalists, naturopaths and other organizations of the kind. When examined the alleged duration of the training is almost invariably found to be fictitious. But more important than duration is the question of quality of training and here the osteopathic colleges in the United States have been again and again shown up as offering wholly inadequate education in every branch of the sciences which

go to the study of medicine. The American Medical Association which largely takes the place of our General Medical Council in the absence of any body of the same nature in the United States, rendered the most valuable service some years ago in grading the schools in America which profess to give a medical education. These were divided into categories A, B, and C. At the last examination of this association of which I have record it was reported that "none of the osteopathic schools was able to meet the standards of even Class C medical schools" and that standard is below anything which we know of in this country. I am personally interested in this aspect of the question because I believe that the authoritative speech by Mr. Neville Chamberlain (the then Minister of Health) in the debate in the House of Commons on February 9, 1926, on my motion for the regulation of unqualified practice laid down two principles, defiance of which wrecked the recent Bill. These were (1) that it was impossible to accept diplomas from another country, into the value of which we really could not pretend to examine and over the qualifications for which we have no control", (2) "that if the osteopaths want to set up a register in this country the first thing for them to do is to start colleges of their own," colleges which would be inspected by competent statutory bodies like the GMC, and the "curriculum of which would gradually have to conform to something very nearly approaching the normal [medical] curriculum of this country."

A well-documented report produced under the auspices of the Committee on the Costs of Medical Care in the United States and published in 1932 by Louis S. Reed, Ph.D., gives a rather different picture of the present position of osteopathy in the United States from that painted by Dr. Kelman Macdonald. Reed's figures show osteopathy as a declining cult—for example, the chiropractors (16,000) were more than twice as numerous as the osteopaths (7,650). Chiropractic, "discovered" by Palmer, is an obvious imitation of osteopathy. To quote Reed: "In osteopathy all disease is due to obstructed circulation of the blood, in chiropractic it is due to obstructed passage of nerve force. But while the osteopaths have largely forsaken their formula, the chiropractors, wise in their generation, have stuck to their shibboleth in all its appealing simplicity, and have consequently beaten their competitors out of the field. It is this very inconvenient and successful rivalry which may explain the present desire of American osteopaths to find new fields for exploitation. Indeed the recent Bill has been described as 'an artless effort to establish a monopoly in this country for the American osteopathic colleges and hitherto there has been no marked enthusiasm on the part of osteopaths to fulfil Mr. Chamberlain's requirement of a properly constituted British school enforcing a curriculum comparable to that demanded of the registered medical practitioner. They have had ten years in which to put their house in order and they have not begun to do so."

I may say that I have quite recently been in communication with two members of Parliament who have been protagonists in promoting registration for osteopaths in this country, and who have declared to me their resolve to proceed no further with this effort until such a school is operating. Can Dr. Kelman Macdonald give further information regarding the steps which he declares that "qualified osteopaths in this country" (practically all of whom are diplomates of American schools) have taken in this respect?—I am, etc.,

E. GRAHAM LITTLE.

London W 1 May 17

SIR—In Dr. Kelman Macdonald's letter in the *Journal* of May 15 (p. 1046) he quotes a statement of mine that "to maintain a tissue in a healthy state regular normal fulfilment of the functions of the arterial, venous and lymphatic circulations is essential, and this is even more so when a joint has been injured" and then he asks if such a statement is so far removed from the definition which he gives of osteopathy. May I point out that this comparison is valueless unless at the same time I agree that lesions as described in osteopathic pathology exist and are capable of interfering with the blood supply of the tissues. Dr. Kelman Macdonald is fully aware that he and I are not in agreement on this material point.

It is regrettable that much of the controversy on osteopathy is complicated and confused both by the general public and by certain enthusiastic medical men who advocate it as the result of loose comparisons of this type which wittingly or unwittingly imply a meaning obviously never intended—I am, etc.,

London, W 1 May 24

MORTON SMART

Angina Innocens

SIR—The last paragraph in Dr. Albert Fitzgerald Peel's letter (*Journal* May 22, p. 1088) in which he objects to the term 'angina innocens', reads as follows: "It is rarely, if ever, necessary to give a name to the syndrome in talking to a patient—all that is required is to explain the mechanism of the pain that it is not due to heart disease, and that recovery will occur. I heartily agree with this and submit that it is a complete and logical reply to his main objection to the use of the term 'angina innocens'. A patient is not told 'you have aortic regurgitation' or 'nodal rhythm'. A medical term is for the use of medical men. Medical men do not shrink from the scientific use of words like pernicious malignant, terminal or progressive. But a doctor needs an accurate descriptive label to express his mental concept."

The term 'angina' itself largely derives its sinister significance from the loose use of words. We now realize that coronary thrombosis was the cause of the painfully fatal cases described in the old textbooks. In view of this connotation there is some sentimental and even scientific justification for the abolition of the use of the vague label 'angina' altogether. But are we to talk of 'coronary' cardalgia of effort, spasmodic coronary cardalgia innocens? The word 'angina' has become too deeply rooted for eradication, and the best that we can do is to add accurate qualifying phrases or words. It is essential that the different types of cardiac pain be accurately labelled and accurately pictured mentally in order that their individual clinical characteristics be recognized for the treatment and prognosis differ with each type.

I frequently see patients with 'angina innocens' who have been vaguely labelled 'angina' and in whom the clinical picture of the innocent syndrome is perfectly distinct and characteristic. The reason for these common mistakes in diagnosis is largely that since the label 'pseudo angina' has quite rightly fallen into disuse no other useful descriptive term has arisen: the result is that the clinical characteristics of the innocent variety of cardiac pain are not clearly remembered.

Without a definite label a condition ceases in the minds of most individuals to possess a definite clinical entity. Accurate definition, mental or verbal, is a necessity for accurate thought or expression. 'Angina' is the traditional term for a pain which is felt in the precordium, radiates to the arm and is related in one way or another

to exertion. The qualification of this label by the terms "spasmodic," "of effort," and "innocens" appears to me to yield the simplest solution to what is admittedly a difficult problem—I am, etc.,

London W 1, May 21

GEOFFREY BOURNE

Intra-epidermic Vaccination

SIR—I am afraid that as a result of the efforts which nowadays we are so much encouraged to make in an endeavour to minimize the ill effects of vaccination some of us may be in danger of losing sight of the object for which we perform this operation. Considered in relation to the protection of a subject against small pox the act of vaccination, however performed, in itself signifies next to nothing—it is the immediately subsequent course of events which is all important.

Dr Peirce, in his interesting contribution to this subject (*Journal* May 22, p 1066) well illustrates my point when he states: "In the event of a case of small pox occurring in a large passenger liner it is imperative that the method [of vaccination] adopted should be simple, speedy, efficient, economical, and above all leave as few ill effects as possible." (My italics.) Now I maintain that in such circumstances the efficiency of the vaccination is the thing which really matters, and that the ill effect most to be dreaded is an attack of small pox in one of the contacts. In the presence of small pox any procedure which may reduce the chances of an undoubted take in a susceptible subject or of an easily recognizable specific reaction in a partially immune is surely unjustifiable, and for this reason, for example, it is inadvisable, when the establishment of an immunity is an urgent necessity, that the number of insertions of vaccine lymph should be less than two. It may be that in the hands of those who are skilled in the art of performing intra-epidermic vaccination and in interpreting the immediately subsequent happenings the method described by Dr Peirce gives results which are satisfactory as regards the immunization of contacts (we have not been given any data on this all important point), and it may be that my small experience of the method—in circumstances almost identical with those postulated by Dr Peirce—was an exceptionally unfortunate one, but I do urge that, at least in the presence of small pox, our aim should be the production of a successful vaccination in the shortest possible time, and by a method which admits of the least possible chance of failure.

In parenthesis, it may be added that Dr Peirce's reference to the freedom from post-vaccinal encephalitis enjoyed by many hundreds on whom intra-epidermic vaccination has been performed in the Port of Liverpool is of small value—for, so far as I am aware, no substantial evidence has ever been brought forward to support the suggestion that the method or type of vaccination, or even the number of insertions, used has any bearing on the incidence of acute perivascular myelinolysis in the central nervous system—I am, etc.,

Dartford May 23

J PICKFORD MARSDEN

Cancer of the Breast

SIR—I have read with interest Dr John E. Ryan's letter on cancer of the breast in the *Journal* of May 15 (p 1045). I agree with him that there is need for more concentration on the problem of prevention of metastases.

It is of course very true that metastases do all the killing and it is when they occur that surgery and irradiation (by x rays and gamma rays) alone are alike

powerless to effect a cure, though irradiation is very useful as a palliative and a means of prolonging life. It was largely for these reasons that the selenide treatment of cancer, as set forth by Todd, appealed to me. It appeared to offer some prospect of dealing effectively with the disease when it had spread beyond the primary focus—in certain cases at any rate. The treatment is definitely an attempt to get at the root of the trouble and to render assistance to the body in a natural process of cure. As such it should make an appeal to all of us, and it may, I think, supply a partial answer to Dr Ryan's statement that "there is no known means of prevention" of metastases. No doubt it is very imperfect, and much revision may be required, but at any rate it is a step in the right direction, and has unquestionably produced some good results.

The dread of cancer in the public mind—and in the professional mind too—is a very serious thing when it comes to the question of treatment of an individual who is suffering from the disease. The main cause of this dread has been our inability to deal with the spread of cancer through the body. It would be an enormous gain if we were able to restore hope by assuring sufferers and their friends that cancer even when well advanced, is not necessarily an incurable disease, and there would then be little need to practise that deception of the patient about the nature of his malady which is so trying and, in my opinion, often unconvincing and ill advised—I am, etc.,

Brighton, May 17

W BARRINGTON PROWSE

Contralateral Artificial Pneumothorax

SIR—In an annotation in your issue of May 15 on contralateral artificial pneumothorax there appears the following extraordinary statement "since it is unlikely that any breathing occurs in the diseased area even before the pneumothorax is induced." The matter under discussion being pulmonary tuberculosis, we are at a loss to reconcile this with the modern teaching on the subject. The only conditions in which we can imagine air failing to enter the diseased area are massive collapse and pneumonia. Both of these are complications of the disease but of sufficient rarity to render invalid any generalizations therefrom. Adventitious sounds being evidence of air entry, we feel that if the statement quoted is accepted the presence of moist sounds must be taken as conclusive proof of the absence of underlying disease. Hence we are to believe that one of the most important signs clinically of tuberculosis is valueless. Experience goes to prove that this is not the case.

Later there appears the statement "It is essential that the mediastinum be mobile and that the pneumothorax be kept at a negative pressure, so that the respiration in the 'collapsed' lung is little reduced." The intrapleural pressures are so dependent on adhesions that in some cases a positive pressure might be achieved with a minimum of air, and the respiration be still little reduced. On the other hand, if the pleura is entirely free almost complete deflation of a lung may be achieved without ever raising the pressure to atmospheric level. Needless to say the respiration in a lung deflated to such an extent would be very greatly reduced.

After inferring from experimental work that the benefits of this type of pneumothorax accrue from the increased vascularity of the other more diseased lung your commentator deduces that the ideal indication for a contralateral pneumothorax appears to be a large or recurrent haemoptysis from an adherent lung. The unexpected is

constantly happening in medicine but it seems probable that the increased vascularity created in the diseased lung will result in increased haemoptysis.

The method of treatment under discussion has not received much encouragement in this country although there would appear to be some considerable foreign literature on the subject. In reading this article we are forced to the conclusion that though the treatment may be good the logic is bad—We are, etc.

G. S. ERWIN
C. A. LILLCRAP

Brompton Hospital, May 21

Hermaphroditism

SIR,—Mr Chapple, in his article on hermaphroditism did not state the gonadotropic hormones found in the urine and blood before and after operation. Would not these findings indicate the quantity and type of gonad tissue left in the body? Are not the causes of homosexuality both psychological and physiological? Thus the male homosexual may be a man who, deeply admiring his father, loves masculinity, or who, loving his mother rejects all women as falling short of the mother ideal and so turns to men, or who, loving his mother, feels incestuous guilt in marrying the maternal woman and so turns to men, or who (as Freud might tell us) has a fear that woman will suck the life from him and from his bank balance in retribution for his sucking of the breast. Surely these abnormal people would make unhappy homes, and it would not be wise for us to encourage them to marry. There cannot be much danger of these influencing normal people to follow their practices except in those circles where homosexuality is 'fashionable'. So we need hardly fear that their mode of living will lower the birth rate. Regarding the physiological causes, did not Steinach and Voronoff cure male homosexuals (altering their emotional attitude) by grafting normal testicular tissue?—I am etc.,

Edinburgh May 14

Intraperitoneal Haemorrhage from a Graafian Follicle

SIR,—I am indebted to Mr J. C. Leedham Green (*Journal* May 15, p. 1045) for pointing out that both his cases were proved histologically to be cases of haemorrhage from lutein cysts. My artless assertion "as he is pleased to call it that my case was one of haemorrhage from a Graafian follicle" was based on the fact that the haemorrhage occurred exactly mid-menstrually. Would Mr Leedham Green venture to suggest in the absence of any irregularity of menstruation such as would be caused by the persistence of a luteal body that the haemorrhage was in fact from a corpus luteum? Unfortunately material is sometimes mislaid between theatre and pathologist but I think the time of occurrence is definite enough to justify my artless assertion.

The cases reported by M. J. Bennet Jones (*Journal* March 13, p. 585) were also haemorrhages from Graafian follicles. I reported my case because it added another to a growing list and seemed to suggest that haemorrhage can apparently occur (1) from lutein cysts either during or immediately after a period as in Leedham Green's first case or immediately before a period as in Leedham Green's second case and (2) from a Graafian follicle when it must be mid-menstrually since the time of ovulation seems to be generally agreed upon in at least 80 per

cent of cases. The other correspondents unfortunately do not give the time of the cycle at which haemorrhage occurred, which is the real point now at issue.

On re-reading the correspondence I was impressed by the following points: (a) there was usually a history of dysmenorrhoea; (b) pain radiated to the epigastrium; (c) luteal haemorrhages were more severe when they occurred; (d) there was dysuria, even in the absence of gross haemorrhage, which I tentatively (this time!) suggest may be accounted for by the innervation of ovary and bladder from the hypogastric plexus. Does not classification assist more than destructive criticism?—I am etc.,

Highbridge, Somerset, May 17

CRESSWELL DAVIS

Accidental Avulsion of Flexor Tendon

SIR,—On February 5 the left hand of an able scaman aged 59 years, was dragged into a pulley connected by

a steel rope to an electrically driven winch. The terminal phalanx of the middle finger was torn off and the attached superficial flexor tendon was avulsed from its muscular attachment and hung as a strand eleven inches long from the phalanx. I enclose a photograph of the specimen.

The patient was seen again on April 22. There was slight power of flexion in the finger, so that the attachment of the deep flexor tendon appears to be intact.—I am etc.,

PHILIP SIMON

Trachoma from Spain?

SIR,—Lord Lloyd in the House of Lords last night performed a public service by asking a question as to the incidence of trachoma among the refugee children from Spain who have arrived in this country. It is known that in many of the provinces of Spain the disease is practically universal. Lord Lloyd was informed that a voluntary body called the National Joint Committee on Spanish Relief had sent some doctors out to examine the children before they left Bilbao. It is not reported that any of these gentlemen had any experience of trachoma, or even any special knowledge of ophthalmology.

The examination of the eyes of 4,000 children by the port medical officers on arrival at Southampton was an absolute impossibility. It is therefore still unknown what proportion of the children if any is trachomatous. The difficulty in making a diagnosis in the early stage of the disease, its contagious nature, the long period required for treatment, and its devastating effects on visual acuity make it important to decide the matter.

However if the children are to be kept segregated in camps or in Salvation Army homes no danger will accrue. If on the other hand a few of them are trachomatous and are placed temporarily in homes in contact with others whether children or adults there is every expectation of a recrudescence of the disease in this country. In this matter the responsibility of the Ministry of Health is very great.—I am etc.,

A. F. MACCALLAN
President of the International Organization
against Trachoma

London W.1 May 26

Obituary

FREDERICK EDGE, MD, FRCS

Late Surgeon, Wolverhampton Women's Hospital, and Birmingham and Midland Hospital for Women

The death occurred in a Wolverhampton nursing home on May 17 of Dr Frederick Edge at the age of 73. He had been in failing health for the past few weeks.

Born at Goos, in Russia, on August 3, 1863, son of Frederick Edge of Halliwell, he came to England when a boy of 10. His early education was at Owens College, Manchester. From there he passed on to St Thomas's Hospital, London, and also studied in the medical schools of Munich, Vienna, Dresden, and Birmingham. He obtained the degree of BSc Lond in 1884, BS in 1886, and the MD in 1890. He obtained the FRCS(Eng) in 1889, and was also a member of the Royal College of Physicians of London. In 1891 he came to Wolverhampton, and was shortly afterwards appointed an honorary surgeon at the Women's Hospital. He took an active part in the development of this hospital, and during his period of service there it expanded from being located in a private house to its present large premises overlooking the West Park. In 1897 he was appointed an honorary surgeon to the Birmingham and Midland Hospital for Women, and retired as its senior surgeon in 1933 after thirty-six years' service. He was also an honorary surgeon to the Birmingham Maternity Hospital and for many years an examiner to the Central Midwives Board. Among other offices which he held were those of president of the Staffordshire Branch of the British Medical Association, president of the Midland Obstetrical and Gynaecological Society, and president of the Midland Medical Society. He made numerous contributions to the medical press on gynaecological and obstetrical subjects, and was also a co-translator of *Dührssen's Manual of Gynaecological Practice and Midwifery*. When the British Medical Association held its Annual Meeting at Birmingham in 1911 he was vice-president of the Section of Obstetrics and Gynaecology. In addition to his professional activities Dr Edge took a considerable interest in the public life of Wolverhampton and served on the Town Council from 1897 to 1904.

With the passing of Dr Edge the Midlands has lost a surgeon whose skill and clinical acumen will be long remembered by those who had the good fortune to be associated with him in his work. His energy was untiring and enabled him to carry on a busy consulting practice in Birmingham in addition to one in Wolverhampton. His kindly nature endeared him to a very great number of grateful patients and his equable temper remained unruffled through the busiest days. He possessed a very subtle sense of humour which made him an attractive companion and gave a peculiar charm to his character. A man of wide literary sympathies, he was well informed on a great number of subjects both professional and otherwise. He had a special gift for languages due no doubt to his early upbringing, which led to his enjoyment of travel in foreign countries. He is survived by a widow, two sons, and a daughter, to whom we would convey our deepest sympathy.

H N L

J H S writes: In the week that Frederick Edge died there appeared in the *Journal* an article on *Perspective and Poise in Practice*. These words epitomize the whole

personality of Dr Edge, for he possessed these qualities in relation not only to practice but to the art of living itself. Endowed with an unusual facility for friendship, which found no difficulty in bridging a disparity of years amounting often to half a lifetime, the love and veneration in which he was held is no matter for surprise. His passing touches many of us deeply. To these qualities was added a certain flavour of individuality—both in point of view and its expression—which derived perhaps from the mixture of Slav and Saxon temperament in his veins, and added point to his personality, marking him off from the mean of the normal man. His professional life was spent in Birmingham and Wolverhampton. To the latter town (from which these notes are written) his services were immense. To mention but one point from the many that spring at once to mind, the fusion of two hospitals is rarely accomplished without friction between the numerous personalities involved, but the amalgamation between the Royal Hospital and the Women's Hospital at Wolverhampton was saved from this very largely through the presence of Dr Edge in our midst. He was made the first chairman of the Medical Committee of the new hospital, and so rare a power did he show of smoothing difficulties, and of keeping us all not only happy and agreeable, but—so rare in such committees—to the point as well, that what had invariably been a yearly tenure was in his case by unanimous desire made into a triennium. Whether in practice, at the bridge table, at the deciding putt on the eighteenth green, or in the presence of some administrative or other difficulty, Frederick Edge was a connoisseur of life with a zest—and a sagacity—all his own. We shall not easily see his like again.

A H FIRTH, M.A., MD

Late Medical Superintendent Worcester County Mental Hospital

Dr Arthur Marcus Firth died on May 17 following, an illness lasting on and off for four years, but which culminated with startling suddenness during a period of convalescence. He was born in Edinburgh 62 years ago, of an old Orkney family, and was educated in Daniel Stewart's College, Edinburgh. He then entered Edinburgh University, where he graduated M.A., and took the M.B., Ch.B. in 1901. He proceeded M.D. in 1913, his thesis being 'The Pupil and its Reflexes in Insanity'. Following qualification he held posts as house-surgeon and house-physician in the Edinburgh Royal Infirmary and later joined the staff of the South Yorkshire Mental Hospital, Wadsley, near Sheffield, in 1904, and worked there as assistant medical officer until 1914. He was then appointed deputy medical superintendent of the Worcestershire Mental Hospital, Barnsley Hall, Bromsgrove, and held that post until his promotion to medical superintendent in 1933. From January 1918, until May, 1919, Dr Firth held a commission as captain in the R.A.M.C., and gave valuable service at the Lord Derby War Hospital at Warrington. In April, 1937, he tendered his resignation to the Visiting Committee owing to continued ill health and in accepting this with deep regret the committee passed a resolution, 'That the cause of Dr Firth's resignation had been a source of extreme regret and sorrow to them and that they felt that the loss of Dr Firth's efficient and valuable services first as deputy medical superintendent and later as medical superintendent for nearly twenty-three years was a severe blow to the hospital. He was buried in the Comeby Bank Cemetery, Edinburgh, on May 21, and simultaneously a memorial service was held in the hospital church, attended by many friends. He was a member of the British Medical Association for thirty-three years, of

the Royal Medico Psychological Association, and of the Midland Medical Institute, Birmingham

"A S" writes Dr Firth was extremely conscientious in all he attempted, never stinting himself in his endeavours, quiet and reserved in disposition, generous and sympathetic, always making the interests of the staff and patients his own. He was intensely loyal, painstaking, far-seeing and enthusiastic, a most competent and successful administrator, a great scholar, a prolific reader of medical books particularly those dealing with psychiatry. He was always a keen believer in the out-patient work of a mental hospital, and he helped to establish and later personally supervised the out-patient psychological clinics held at the Corbett Hospital, Stourbridge, and at the General Hospital, Birmingham. Outside his work he had few interests, he was fond of music and photography, and loved to spend his odd hours, which were all too few, wandering about the lesser-known roads of Worcestershire and district exploring and later passing on his "finds" to his friends. His death has left a gap in the school of British psychiatrists and in the hearts of those who knew him.

Medical Notes in Parliament

In the House of Lords on May 25 the Coal Mines (Employment of Boys) Bill and the Children and Young Persons (Scotland) Bill were read the third time, and passed. On the same day the Lords agreed to the Commons amendments in the Diseases of Fish Bill, and read the Widows, Orphans, and Old Age Contributory Pensions (Voluntary Contributors) Bill a second time.

The House of Commons has this week discussed the Civil List and the Board of Trade Estimates. The Government arranged to give time on May 28 for the concluding stages in the Commons of the Marriage Bill. It was expected that about the same date Mr Neville Chamberlain would succeed Mr Baldwin as Prime Minister, and that the personnel of the reconstituted Government would be announced.

The text of the Finance Bill was issued on May 24. Clause 16 provides that professions are not liable to the National Defence Contribution tax.

A Standing Committee of the House of Commons continued its consideration of the Factories Bill on May 25. Major Proctor moved an amendment to bring film actors and actresses within the scope of the Bill, but Mr Geoffrey Lloyd opposed this. He promised however to report the matter to the Home Secretary, who would consider whether there should be an inquiry into the question of protection for film actors or actresses. The Committee completed consideration of all but the new clauses of the Bill. Discussion of these was to begin on May 27.

Committee on Abortion

On May 24 Mrs TATE asked the Minister of Health if he was in a position to give the terms of reference and the personnel of the Interdepartmental Committee on Abortion the decision to appoint which by the Home Secretary and himself was announced when the recent report on maternal mortality was issued.

SIR KINGSLEY WOOD said that the terms of reference to the Committee were "To inquire into the prevalence of abortion and the present law relating thereto and to consider what steps could be taken by more effective enforcement of the law or otherwise to secure the reduction of maternal mortality and

morbidity arising from this cause. The members of the Committee would be Mr Norman Birkett K.C. (chairman), Mrs Stanley Baldwin, Lady Ruth Balfour, Sir Comyns Berkeley, Mr H. A. de Montmorency, Dr T. Watts Eden, Lady Forber, Sir Rollo Graham-Campbell, Dr G. C. M. McGonigle, Sir Ewen Maclean, Captain M. P. Pugh, Mr W. Bentley Purchase, Mr C. D. C. Robinson, Mrs Thurtle, and Lady Williams. Communications relating to the work of the Committee should be addressed to the Secretary, Committee on Abortion, Ministry of Health, Whitehall, S.W.1.

Spanish Refugee Children and Trachoma

In the House of Lords on May 25 LORD LLOYD asked the Government what if any arrangements were being made for the segregation of refugee children from Spain. He said that his solicitude in this matter resulted from correspondence he had had with Mr A. F. MacCallan, an ophthalmic surgeon who had done much to relieve blindness through the Nile Valley. Mr MacCallan and the President of the Royal Society of Medicine had written to the Minister of Health pointing out how grave was the danger of introducing these Spanish children unless careful examination and segregation were carried out. The fear was that these children might introduce trachoma, a contagious eye disease which was obstinate to treat and led ultimately to blindness. The United Kingdom only rid itself of this scourge of trachoma by a rigid application of the Aliens Act of 1920. In its early stages the disease was hard to detect, except by experts and it was a disease which was known to ravage the whole of Northern Spain. He saw it reported that the Basque children were not to be kept in one camp but were to be distributed about the country. Owing to our comparative immunity from this disease it was doubtful whether there were many oculists in this country capable of detecting trachoma in its early stages. Since the necessary examination was long and difficult he asked if the Government was satisfied that the necessary precautions had been taken.

THE MARQUESS OF DUFFERIN AND AVA, replying for the Home Office, said that all the arrangements for bringing these children to England were made not by the Government but by the National Joint Committee on Spanish Relief, a voluntary body which had accepted all financial responsibility for the children. The Committee sent out doctors to examine the children before they left Bilbao. Trachoma in its opinion was uncommon in the Basque country. The only cases discovered were in children from other parts of Spain. Among those who were selected to be evacuated the doctors found only two cases of this admittedly dangerous contagious disease. Those two cases were excluded from the ship. The Committee had made every effort to make sure that no child should be admitted to England suffering from any contagious or infectious disease. It had also taken full responsibility for the care and maintenance of the children in this country and it was fully understood by the Committee and all responsible for this evacuation that the presence of these children here would be of short duration. The interest of the Government in the matter was limited to securing that practical plans had been made by the Committee for the maintenance of the children in institutions and homes and to making sure that on arrival they were medically examined.

For the moment the children had been placed in a temporary camp at Southampton which was not accessible to the general public. Nobody could get in without a special pass. The children were not allowed out without special permission and when the latter left the camp it would be on the advice of the medical officers in charge and the local health authorities. When that permission had been obtained the children would go in fairly large units to various places where they would be supervised by Basque priests and teachers. On arrival at Southampton the children were submitted to a medical examination more searching than would have been the examination if they had arrived individually. The medical officers in charge were surprised to find how little their experiences in a beleaguered city had affected their health.

The Services

ARMY MEDICAL SERVICES

The War Office announces the following appointments

Colonel R W D Leslie OBE., Officer Commanding the Queen Alexandra Military Hospital Millbank SW has been selected for promotion to the rank of major general from August 10 1937 and to be Deputy Director of Medical Services Northern Command York in succession to Major General G G Tabuteau DSO who is taking up the appointment of Director of Medical Services in India

Colonel A D Fraser, DSO MC., who commands the R A M C Depot and Training Establishment at Aldershot, has been selected for promotion to the rank of major general from October 13, 1937 and to be a Deputy-Director of Medical Services in India in succession to Major General D S Skelton, CB DSO Honorary Physician to the King who will vacate the appointment on completion of four years service as a major general.

DEATHS IN THE SERVICES

Brevet Colonel EDGAR JENNINGS Bengal Medical Service (ret.) died in London on May 12, aged 72. He was born at Outakamand on August 3 1864 the son of Lieutenant C J Jennings of the Madras Staff Corps and was educated at King's College London taking the MRCS and L.S.A. in 1886. He subsequently took the DPH at Cambridge in 1909. He entered the IMS as surgeon on March 30 1889 became lieutenant-colonel after twenty years service and received a brevet colonelcy on January 1 1916 for war service. He retired on February 5 1920. He served in the war of 1914-18 and was mentioned in dispatches in the *London Gazette* of April 5 1916.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on May 18 the following appointment made by the Board of the Faculty of Medicine and approved by the General Board of the Faculties was approved. B G Macgrath B.S. M.A. DPhil. Fellow of Exeter College as University Demonstrator in Pathology from May 1, 1937, to September 30 1941.

Notice is given that the Readership in Bacteriology is vacant, and that Electors will meet to elect a Reader on Tuesday June 1.

UNIVERSITY OF LONDON

At a meeting of the Senate held on May 19 with the Vice-Chancellor Mr H L Eason M.D. M.S., in the chair Mr John Kirk M.B. F.R.C.S.E. was appointed as from October 1 to the S A Courtauld Chair of Anatomy tenable at the Middlesex Hospital Medical School.

The title of Professor of Morbid Anatomy in the University was conferred on Dr W D Newcomb in respect of the post held by him at St. Mary's Hospital Medical School.

The Dunn Exhibitions in Anatomy and Physiology for 1937 were awarded to Mr J W Paulley Middlesex Hospital Medical School and Mr Philip Harvey Guy's Hospital Medical School respectively.

Mr W G Spencer has been reappointed by Convocation as representative of Medicine in the Senate for the period 1937-41.

LONDON HOSPITAL MEDICAL COLLEGE

The prizes for 1937 will be distributed to students of the London Hospital Medical College by the Minister of Health Sir Kingsley Wood on Tuesday July 6 at 3 p.m. in the College Library.

GUY'S HOSPITAL MEDICAL SCHOOL

An Entrance Scholarship in Science of the value of £100 has been awarded for 1937 to P L Masters, Alleyn's School Dulwich.

Medical News

To commemorate the founding and planning of the City of Adelaide in 1837 a meeting will be held in the Assembly Hall of the Royal Empire Society, Northumberland Avenue, WC2, on Monday, May 31, at 4.30 p.m., when Dr Thomas Adams will give a lecture, followed by an address by Sir William Sowden of Adelaide.

A meeting of the Kensington Medical Society will be held at St Mary Abbots Hospital Marloes Road, W., on Tuesday, June 8, at 8.30 p.m. when Mr V B Green-Armytage will speak on 'The Value of Hysterosalpingography in General Practice'.

A meeting of the International Faculty of Sciences will be held in conjunction with the Institution of Electronics and the Institute of Chemist-Analysts at the Gaumont-British Theatre, Film House, Wardour Street, W., on Monday, May 31, at 7.30 p.m., when Dr S Monckton Copeman, F.R.S., will give a lecture on 'Experimental Work Bearing on the Treatment of Cancer'. A discussion will follow.

The annual provincial meeting of the Tuberculosis Association will be held as a joint meeting with the North-Western Tuberculosis Society at the Central Library, Manchester, on Thursday, Friday, and Saturday, June 10, 11, and 12. The following papers will be read: 'How Long Should Collapse Therapy be Delayed?' Dr Geoffrey Marshall and Mr H Morrison Davies; 'Bronchiectasis in Pulmonary Tuberculosis,' Mr J E H Roberts; 'Pleural Effusions after Thoracoscopy,' Dr O M Mistal; 'Treatment of Unilateral Pulmonary Tuberculosis,' Dr P J L. De Blocme; 'Difficulties in Dealing with the Tuberculosis Problem,' Professor A Ramsbottom and others; 'Use of the Tomograph,' Dr J B McDougall; 'Artificial Pneumothorax in Children,' Dr C D S Agassiz. The annual meeting will be held at 6.20 p.m. on June 10, and the annual dinner at 7.30 p.m. at the Midland Hotel on June 11. A visit to the Manchester Sanatorium has been arranged for Friday afternoon, and to other sanatoria on Saturday. Further information may be obtained from the honorary secretary, Tuberculosis Association, 26, Portland Place London, W1.

The sixteenth congress of the Journées Médicales de Bruxelles will be held in that city from June 19 to 23, under the presidency of Professor Albert Dustin, rector of the university. It will be opened by Dr G Duhamel of the Académie Française and among the subsequent speakers will be Sir Joseph Barcroft and Drs Danielopolu, Jeanneney, Castellani, Sorel, Rathery, Veraguth, Brull, Lépinay, Pautrier and Olenick. The excursions will include a visit to the Albert Canal, and there will be receptions, banquets, and theatrical performances. A detailed programme is being prepared. The fee for membership of the congress is 100 francs (Belgian), and further information may be obtained from Dr R Beckers, the general secretary, 114, Rue Belliard, Brussels.

Among the recipients of King George VI's Coronation Medal are the following members of the Metropolitan Police Medical Service: Chief medical officer, Dr Isaac Jones, consulting surgeon, Mr Max Page, assistant physician, Dr H B Russell, dental surgeons, Mr Lloyd Williams and Mr O'Donnell, divisional surgeons, Drs F J Lawson, W G Johnston, A R Moore and P B Spurgin.

The *Indian Medical Gazette* for April is a special tuberculosis number and contains five articles on various aspects of collapse therapy for pulmonary tuberculosis.

The centenary of the foundation of the German Association of National Science was celebrated in Posen on May 9.

An outbreak of psittacosis has recently occurred in Buenos Aires and the city of Tandil.

Letters, Notes, and Answers

LETTERS, NOTES, ETC

Short wave Therapy

Dr P P DALTON (London W1) writes. In the *British Medical Journal* of May 8 (p 1008) Dr H J Taylor of the St John Clinic draws your readers attention to quotations from a report recently issued by the American Council of Physical Therapy regarding its work of the past year in which it states "The Council felt that the general practitioner should understand that when he buys a short wave diathermy machine he is simply purchasing an apparatus capable of producing heat. In the light of available evidence it has absolutely no specific action. This quotation is presumably issued by Dr H J Taylor as a counterblast to my article published in the April number of the *British Journal of Physical Medicine* entitled 'Low Intensity Short waves (113 metres) Preliminary Observations Concerning their Effects on Living Tissues' in which I demonstrated the effects of a practically non-heating short wave apparatus on frog nerve-muscle preparations in article which has attracted much attention both at home and abroad. As Dr Taylor has published this throughout the medical press it is only right that the observations appended to his letter by Dr King Brown the medical editor of the *British Journal of Physical Medicine* in the May number of his journal be equally brought to the notice of your readers. We think our readers will probably suspend judgement on this knotty question of the specific action of short waves in view of recent investigation by authors both here and on the Continent. It should at least be noted that the Council of Physical Therapy gives its judgement on the present available evidence and we would venture to suggest that new evidence is coming to hand as indicated by the interesting communication from Dr Dalton in our last (April) issue which will have to be taken into account in any future discussion on the effects of short wave treatment. Also I suggest that the term 'short wave diathermy' should be confined strictly to powerful machines producing heat. The proper term for the low intensity treatment should surely be short wave therapy. The word diathermy implies that heat is produced in the tissues.

An Orthopaedic Nursing Certificate

Hitherto the orthopaedic hospitals of this country of which there are over thirty have issued certificates of proficiency to their probationer nurses on completion of training, based on their practical work and on examinations held at the various institutions. This system has provided no criterion by which the standard of training provided in the various hospitals can be compared. In an attempt to secure greater uniformity and standardization a subcommittee of the Central Council for the Care of Cripples has after investigation and deliberation decided with the approval of the council to establish an orthopaedic nursing certificate based on a uniform syllabus acceptable to the majority of orthopaedic hospitals. The certificate is not intended necessarily to replace that issued by any individual hospital but to provide a supplementary means of assessment of training received. No attempt to change the methods of treatment of patients or training of nurses is being made, nor is it suggested that the recruitment of the more senior members of the nursing staffs of orthopaedic hospitals should be amended in view of the establishment of this certificate.

A Warning

Dr C C H CHAYASSE (London W9) writes. I was visited recently by a man giving an address in Watford. He said he had recently come out of gaol and was starving. He claimed contemporary studentship with many famous men at Bart's and said also that he was an Oxford graduate and an ex naval surgeon. He was a well spoken man of about 70 with slight left facial paralysis and tattoo mark at the back of the right hand and arm. It seems that he is not a qualified medical practitioner.

Pink Disease

In an annotation on this subject (*Journal* May 22 p 1077) reference to an original article by A J Wood and I Wood is given as *British Medical Journal* 1935 1 105. This should be *British Medical Journal* 1935 2 527.

All communications in regard to editorial business should be addressed to THE EDITOR BRITISH MEDICAL JOURNAL B.M.A. HOUSE TAVISTOCK SQUARE W.C.1

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1 on receipt of proofs. Authors over-seas should indicate on MSS if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

MEDICAL SECRETARY *Mediscera* *Westcent* London

The address of the B.M.A. Scottish Office is 7 Drumsheugh Gardens, Edinburgh (telegrams *Associate Edinburgh* telephone 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.) 18 Kildare Street, Dublin (telegrams *Bacillus Dublin* telephone 62550 Dublin).

QUERIES AND ANSWERS

Iodine Albuminate

Dr J JACKSON (Dublin) writes. Would any reader kindly let me know (1) if there is any advantage in an albuminate of iodine over simple tincture of iodine for internal use (2) how albuminate of iodine is generally prepared and (3) whether colourless iodine is of less therapeutic value than ordinary iodine for external use in, for example, an oily preparation for rheumatic and pulmonary affections.

Splitting Finger-nails

'STUMPED' writes. Would some reader kindly inform me of the cause and treatment of splitting of the finger nails. My wife while resident in London and Manchester has suffered for some time from splitting and flaking off of the ends of the finger nails. She does ordinary housework and wearing rubber gloves does not seem to have made much difference.

Nascent Iodine Treatment of Tuberculosis

Dr J PIRIE (Leamington Spa) writes with reference to his note published on May 15 (p 1056). I have had so many letters from doctors in Scotland, Ireland and England asking for details that it may be some time before I can answer all their questions but I wish to assure all who have written to me that I shall answer them as soon as possible.

Income Tax

Subscriptions by Panel Committee

'Y' explains that a Panel Committee pays £50 a year to medical charities and has an income from investments which more than covers that amount. Can the committee arrange to make covenanted payments deducting tax therefrom and leaving the recipients to claim the tax back?

.. There would seem to be no great difficulty in the course suggested provided that the constitution of the committee is such that some persons are legally competent to bind the committee for seven years. It is, of course, essential that the payments should be legally eligible throughout the period.

Sickness Insurance Premiums

'J S' pays an annual premium of £19 per annum on a policy to secure payments to cover the cost of a locum tenent during sickness. Is an income tax allowance due?

.. No. There is no relief in respect of premiums for sickness benefit and of course any receipts under the policy are not taxable.

Intestinal Tuberculosis

G. HERTZBERG (*Nord med. Tidskr.* March 5 1937, p. 373) reports from the Grefsen Sanatorium in Norway his observations on tuberculosis of the intestines, which he believes to be the most common complication of pulmonary tuberculosis. He found it at necropsy in seventy-one out of eighty-four cases of pulmonary tuberculosis. Comparing the clinical with the radiological and post-mortem findings, he notes that in pulmonary tuberculosis the only significant clinical sequence of events indicative of intestinal tuberculosis is regular action of the bowels, then constipation, and finally diarrhoea, which is continuous till the patient's death. This syndrome does not occur in cases of pulmonary tuberculosis in the absence of intestinal tuberculosis but its diagnostic value is minimized by its comparatively late appearance for it is a more or less constant phenomenon only in patients with widespread intestinal involvement. Even when the condition proved to be most extensive a quarter of such cases had shown no clinical signs other than constipation, and in the early stage of this disease it was the exception rather than the rule for clinical signs of it to be demonstrable. Diarrhoea was absent in four-fifths of the early cases and in about a quarter of the most advanced cases. Abdominal pain was absent in seven out of every eight early cases and in one out of every three advanced cases. Even emaciation was lacking in about a half of the cases. The author concludes that the clinical diagnosis of intestinal tuberculosis is difficult, because in about every third case there is absolutely no clinical sign of it, and because its general manifestations are identical with those of such common ailments as colitis and appendicitis to which patients suffering from pulmonary tuberculosis are just as subject as other persons. Some of the symptoms of intestinal tuberculosis are also identical with those of gastritis from which the subjects of pulmonary tuberculosis suffer more often than other persons.

420

Suprarenal Cortex Insufficiency

S. THADDEA (*Zbl. inn. Med.* March 20 and 27 1937, pp. 220 and 257 resp.) points out that the cardinal function of cortin the hormone from the suprarenal cortex, is still unknown. The physiology of the cortex is important (1) It is essential to life. Animals with only a suprarenal medulla die. (2) Cortical insufficiency results in adynamic muscles increased viscosity of the blood, lowered resistance to infection and changes in the circulatory system, with lowered heart action and stimulation of the sympathetic nervous system a fall of high blood pressure and changes in the electrocardiogram. (3) The cortical hormone regulates growth and development body temperature fluid output, and general metabolism especially that of proteins carbohydrates cholesterol and creatinine. Suprarenal cortex insufficiency is best seen clinically in Addison's disease the treatment of which condition is restoration of cortical function by (1) high daily doses (50 to 100 ccm) of cortical hormone (2) avoidance of physical and psychical fatigue (3) a diet rich in carbohydrates and vitamins especially C A and B and also rich in salts sodium chloride 5 to 10 grammes daily being given but poor in proteins and fats (4) the institution of alkaline treatment (sodium bicarbonate 10 to 20 grammes rectally) to avoid acidosis and (5) the administration of cytochrome 0.2 gramme daily intramuscularly. Cytochrome prevents inactivation of the cortical hormone through oxidizing and fermentative processes. The possibility of a functional lesion of the suprarenal cortex existing in such conditions as Addisonism general wasting of endocrine origin pluriglandular disturbances,

acute infections, especially diphtheria, and chronic infections, notably tuberculosis, must be borne in mind. Thaddeus has used cortical hormone combined with vitamin C therapy with great benefit in a number of such conditions.

421 Cardiovascular Changes in Avitaminosis

S. WEISS and R. W. WILKINS (*Trans. Assoc. Amer. Physicians* 1936, 51, 341) discuss the nature of the cardiovascular changes in avitaminosis-B in man, the relationship of alcoholic polyneuritis to these conditions, and the clinical effects of administration of vitamin B. Of 912 cases of nutritional deficiency ninety-seven showed cardiovascular disturbances such as abnormal heart rates and rhythms, fatigability, dyspnoea, oedema, etc. In patients who died, the fibres of the myocardium and conducting bundles showed various degrees of hydropic degeneration. There was also intercellular oedema and collagen formation, but there was no relationship between the degree of histological change and the clinical symptoms. In some patients parenteral administration of crystalline vitamin B₁ was followed by improvement, while in patients with no nutritional deficiency the same treatment had no effect on the cardiovascular system. The type of cardiovascular disturbances observed was due to changes in both the myocardium and the vagi, the alteration in the nerves being functional in nature. When associated with alcoholism, polyneuritis and cardiovascular disturbances appeared to be due rather to the associated nutritional disturbance (principally vitamin B deficiency) than to the alcohol itself. In general, the cardiovascular manifestations may depend on certain metabolic factors associated with vitamin deficiency rather than directly on the vitamin deficiency itself. In another study P. M. ZOLL and S. WEISS (*Proc. Soc. exp. Biol. N.Y.* 1936, 35, 259) showed that rats with vitamin B deficiency exhibit bradycardia and electrocardiographic changes which may be abolished by parenteral administration of crystalline vitamin B₁.

Surgery

422

Bilateral Hydronephrosis

H. SMAGGHE (*J. Urol.* January 1937, p. 5), in discussing cases of bilateral hydronephrosis, states that the condition is not uncommon and is usually revealed by intravenous urography. Bilateral hydronephrosis is met with in cases of congenital malformation in lesions of the lower urinary tract causing obstruction in the bladder, prostate, or urethra, or in inflammatory lesions or tumours in the adjacent pelvic organs. These latter conditions bring about uretero-pelvic dilatation, but congenital lesions, of which the most common are abnormal vessels, cause a dilatation of the pelvis alone. Pelvic lesions which may cause bilateral dilatation of the ureters, are most often found in women and include prolapse of the uterus, uterine fibromata, ovarian cysts, and pregnancy. Certain cases of bilateral hydronephrosis show few symptoms, particularly those cases of congenital uretero-pelvic dilatation of primary origin. In other instances the dilatation causes indefinite feelings of heaviness in the lumbar region in pregnancy this symptom is hard to distinguish from muscular fatigue. In typical cases pain may be persistent or intermittent with crises similar to attacks of renal colic, affecting most severely the side on which the kidney is most damaged. The increase in size of the kidneys being bilateral may suggest polycystic disease but the diagnosis can be settled by pyelography. Prognosis in cases of bilateral hydronephrosis is grave, as progressive renal insufficiency leads inevitably to uraemia. In pregnancy, if symptoms occur before the fourth month,

the pregnancy should be interrupted. At a later stage drainage by ureteric catheters may be carried out or in severe cases nephrostomy may be necessary. Nephropexy is indicated in all cases of simple pelvic dilatation after division of the abnormal vessel or adhesions, and also when the dilatation is of uretero-pelvic origin. In cases of infective dilatation nephrostomy should be carried out and the kidney allowed to drain for several months. Twelve cases of hydronephrosis are reported.

423

Wounds of the Face

L. DUFOURMENTEL (*Presse méd.*, March 13, 1937, p. 387) in describing the treatment necessary in wounds of the face, points out that although primary attention should be directed at preventing the spread of infection, this is often not possible as facial wounds are more prone to infection than lesions in any other part of the body, owing to the buccal, nasal, pharyngeal, and other discharges. On the other hand, any such infection is of little moment, as it is seldom grave and does not lead to any complications such as fever, abscess formation, or erysipelas. This is accounted for by the fact that the natural cavities of the face act as drains and the healthy mucosa is well equipped to overcome any source of infection. Early treatment of facial wounds should avoid the removal of any fragments of bone which may be of use for reconstruction unless these fragments are detached. Cautious and restrained treatment is of the utmost importance. Reduction of fractures of the lower and upper jaw should be carried out by a dentist rather than by a surgeon, and should be undertaken as soon as possible. Reduction of fractures of the nasal bones should also be carried out at once as fragments soon become immobilized in a bad position. Emphasis is laid on the care needed to secure accurate apposition of the skin edges in superficial wounds, and the technique of suture is fully described.

424

Prophylaxis of Peritoneal Adhesions

CH. KAPLAN (*J. méd. Ukraine* 1936, 6, 4, p. 1085) maintains that every suture applied to the parietal or visceral peritoneum ultimately adheres to the omentum. These adhesions may necessitate further surgical intervention. Experiments on animals have proved that small fragments of omentum implanted over the sutures prevent the appearance of adhesions when the following rules are observed: (1) the fragment of omentum must not contain any vessels visible to the naked eye; (2) it must be larger than the lesion it covers; (3) the sutures must be completely covered by it; (4) all bleeding must be carefully controlled during the operation; (5) only the part of the omentum near to its fixed border must be used; (6) all the resulting defects in the omentum itself must be covered by peritoneum.

425

Biopsy in Bone Tumours

G. CORYN (*Scalpel*, Liège, March 27, 1937, p. 388) advises that in cases in which the diagnosis of malignant disease can be satisfactorily confirmed by clinical means or radiography biopsy should not be carried out on account of the danger of disseminating the tumour. But in certain cases radiography may be misleading and in two instances tumours reported benign showed microscopical characteristics of malignancy. In one of these cases amputation was carried out by a surgeon who was opposed to biopsy. Certain malignant tumours such as myelomata, hypernephromata, and some osteogenic sarcomata only show localized decalcification in the early stages without any malignant characteristics. Radiology is of very little value in differentiating between an osteochondroma, an osteo-chondro-sarcoma, and a calcified fibro-chondro-sarcoma. Opponents of biopsy advocate watching the development of the tumour until a diagnosis is certain. The author believes it more dangerous to wait until a malignant tumour shows unmistakable signs as it may already have invaded the neighbouring tissues than to

make an early diagnosis by biopsy. It is important that a sufficiently large section of the growth shall be removed and in order to reduce the risk of dissemination of the neoplasm irradiation should be carried out immediately before biopsy and amputation performed as soon as the result is known. Four cases are reported which confirmed the opinion that when clinical and radiographic evidence are sufficient to establish a correct diagnosis biopsy should be avoided but occasionally it is the only certain method of arriving at such a diagnosis.

Therapeutics

426

Treatment of Lupus

H. HAXTHAUSEN (*Ugeskr. Laeg*, April 8, 1937, p. 383) reports from the University Dermatological Hospital in Copenhagen his experiences with diathermy in lupus. This treatment has hitherto enjoyed no great vogue and has been given in the form of massive electro-coagulation of the tissues as in malignant disease. The sequel has been slow healing with extensive and cosmetically objectionable scar formation. Haxthausen has followed Olesen who a few years ago, modified the hitherto conventional diathermy treatment of lupus by a much more conservative technique which entailed less wholesale destruction of tissues. After-treatment with warm rays (solux) and a special dietary regime were also introduced by Olesen with a view to improving the ultimate results. Haxthausen has dispensed with such warm wave after-treatment and only a few of his patients were given a special diet resembling in some respects Gerson's diet. In most cases the treatment required no general anaesthetic and only in some cases was a novocain-adrenaline local anaesthesia employed. In four of the twelve cases recorded a clinically symptom-free cure was effected, and in another four cases the improvement was so marked that a complete recovery might be anticipated. In the remaining four there was little change for better or for worse. As a rule the cosmetic results were surprisingly good. Yet Finsen treatment remains the most reliable form of therapy and should be preferred under favourable circumstances. It is however comparatively costly on account of the time it takes and diathermy may therefore be preferable when the patient can only afford to undergo a brief course of treatment or take ambulant treatment so many times a year. Diathermy is also indicated in those cases of lupus which have resisted the Finsen treatment.

427 H. L. BANBERG and P. KRONER (*Münch. med. Wschr.*, April 9, 1937, p. 569) have used a combination of red light, ectebin, and Grenz rays in the treatment of lupus vulgaris. The red light was obtained from an incandescent electric bulb and a red glass filter. The ectebin was rubbed into the affected skin and the Grenz rays were given in doses of 1,000 to 1,500 r at each sitting. This combined therapy causes an intense reaction in the lupotic foci, resulting in a more thorough destruction of the diseased tissues while at the same time the cutaneous connective tissue is preserved. This improves the cosmetic results. Another advantage is the shortening of the length of time taken for treatment. The authors have been using this therapy for ten years and have never observed any damage from the Grenz rays.

428

Indications for a Sea Climate

H. CURSCHMANN (*Deutsch. med. Wschr.*, April 16, 1937, p. 620) of the University Hospital in Rostock discusses the indications for a sojourn by the sea in the light of recent clinical and experimental investigations which suggest that a sea climate promotes the tone of the sympathetic and lowers the tone of the parasympathetic. The pulse rate, blood pressure, and sugar content of the blood are raised by cold sea baths—signs indicative of increased tone of the sympathetic. On the other hand prolonged

sun baths lower the blood pressure and sugar content of the blood—signs indicative of increased vagus activity. Professor Curschmann considers more fit for hospital and psychotherapeutic institutions than for a seaside resort that ever-dwindling class of patients who suffer from *grosse hystérie* with its confusional states paralyse self-inflicted injuries, etc. A larger group of patients suffering from minor hysterical manifestations referable to the vegetative nervous system however is well suited for treatment by the sea. The two extremes of neurasthenia, the very excitable and the very flaccid should not go to the sea but the vast army between these extremes should profit greatly from it. Clinical experience and recent experimental research agree as to the benefits of the sea-side in general and short sea baths in particular for the subjects of high blood pressure. It is also usually very beneficial for that infinitely varied group of 'sexual neurasthenics'. Cases of nervous dyspepsia, provided that they do not need special dietetic supervision also benefit from a sea climate. Migraine is notoriously amenable to changes in climate and often reacts satisfactorily to a sea climate. Professor Curschmann's general impression is that the therapeutic properties of the seaside in connexion with the ailments discussed are now more generally appreciated than they were.

Diseases of Children

429 Jaundice in Children

MORRIS ASTRACHAN (*Amer J Dis Child* February, 1937, p. 541) reports six cases of icterus gravis neonatorum of which two proved fatal. The condition may occur in the familial or sporadic form in which pregnancy is normal and the infant is delivered normally at term. Jaundice is the most striking feature and it is noted early—it may even be seen at birth. Jaundice occurs in each successive infant with fatal results unless treated early with blood serum. In addition to the jaundice there is pallor, drowsiness and enlargement of the liver and spleen. The stools and urine contain much bile. An increase in the nucleated red blood cell count is always found and is far beyond the physiological limits. The responsibility for making a prompt diagnosis is great for in icterus gravis the immediate transfusion of blood or the administration of blood serum intramuscularly is efficacious and life saving. The mortality of untreated cases is at least 80 per cent. Every child born in a family in which there has been a previous death from icterus gravis should be treated as a potential patient and blood should be given promptly. A summary of recent work on jaundice is given and theories regarding icterus gravis are discussed.

410 Hepatic Disease in Childhood

S. WOLFF (*Klin Wschr* April 17 1937 p. 560) points out that although the pathology of the liver has received much attention in recent years hepatic disease in childhood has been neglected. Latent forms of hepatic disease may be found in children complaining of lassitude, anorexia, nausea and flatulence. They are often extremely emaciated. On examination the liver is found to be slightly enlarged (especially if the child is laid on the left side) tender and it may be hard. Bilirubin and urobilin may be found in minute amounts in the urine sometimes Millon's test is positive. The correct treatment is a diet rich in carbohydrates combined with the administration of dextrose. In rare cases 3 to 5 units of insulin twice daily are necessary. In children bile may be found in the urine and be absent in the stools without the occurrence of jaundice. Such cases may be aborted by the above treatment. According to Wolff catarrhal jaundice in children is nearly always ushered in by persistent vomiting resulting in rapid loss of weight. The specific treatment of this condition consists in the subcutaneous injection of 5 units of insulin and the intra-

venous injections of 20 to 50 c cm of 50 per cent dextrose. The result is dramatic in one case a moribund girl was able to return to school eight days after the first injection. Wolff states that catarrhal jaundice may appear, although rarely, in infants. It must be differentiated from icterus neonatorum by Gmelin's test which is negative in the latter condition. Treatment is exactly similar to that for the older child, the dosage being modified to the age. Wolff believes that the active treatment of these children prevents the occurrence of serious hepatic disease in adult life.

431 Diaphragmatic Paralysis in the Newborn

A. M. A. PERRAULT (*Thèse Paris* 1937, No 208) who records sixteen illustrative cases, states that in addition to the well-known obstetrical paralysis of the brachial plexus there is an obstetrical paralysis of the phrenic nerve. The right nerve is more often affected (eleven cases) than the left (five cases) and in the majority of cases (fourteen) there is an associated paralysis of the brachial plexus on the same side. On the other hand, paralysis of other muscles of the cervical plexus is very rare (two cases). Diaphragmatic paralysis in the newborn appears to be due to several factors, whether traumatic (elongation of the nerve roots or compression of the nerve due to obstetrical procedures) or congenital. The symptoms comprise dyspnoea, cyanosis and digestive disturbances in paralysis confined to the left side. The physical signs can only be detected by radiological examination. The course of these paralysees varies. Death is rare and may be due to pulmonary complications (two cases), or the paralysis may last indefinitely (seven cases) or end in recovery (seven cases). There is no effective treatment.

432 Gastric Acidity in Infants

ALICE STEWART (*Brit J Child Dis* January-March, 1937 p. 1) states that the literature on gastric acidity shows the following facts: (1) there is no evidence of congenital achlorhydria, nor is it present in healthy children, (2) gastric acidity may be lowered by any parenteral infection but is especially affected in chronic gastro intestinal disease, (3) the acidity is lower in infants than in older children. The author's own investigations were carried out in young children divided into the following four groups: (a) iron-deficiency anaemias, (b) previously anaemic children now in good health, (c) other illnesses, (d) healthy children. She concludes that the deficiency anaemias of infancy appear to be caused by pure iron deficiency and are not primarily caused by a failure of gastric secretion. The impairment of gastric secretion found in the anaemic cases seems to be the result not the cause, of the condition. This low acidity however decreases still further the amount of available iron, thus aggravating the anaemia and preventing spontaneous cure. It is possible though not proved that infective states particularly enteritis play a part in the aetiology of the iron-deficiency anaemia of childhood by causing chronic gastritis with suppression of acid secretion.

433 Upper Lobe Atelectasis in Children

M. DE BRUIN (*Nederl Tijdschr Geneesk* March 13, 1937 p. 1124) who records five illustrative cases, maintains that atelectasis of the lung in children mainly occurs in the lower lobe the most frequent causes being foreign bodies accumulation of secretion and glandular swellings. The first two causes almost always give rise to atelectasis of the lower lobe and it is only large glands that cause atelectasis of the upper lobe. The right lung is more frequently affected than the left. In uncomplicated cases the symptoms are few or none, dyspnoea and fever do not occur. The condition is probably often mistaken for pneumonia or interlobar pleurisy. As regards the prognosis atelectasis is often serious because bronchiectasis may develop rapidly unless there is spontaneous reventilation of the affected lung.

Obstetrics and Gynaecology

434 Rupture of the Membranes in Eclampsia

According to B STROGANOFF and O DAVIDOVITCH (*Gynec et Obstét* March, 1937 p 220) the main principles of the treatment of eclampsia have been established, and consist in (1) suppression of the crises according to the first-named author's methods—rest, supervision, narcotization and anti-toxaemic measures, (2) acceleration of termination or induction of labour by measures from which *accouchement forcé* or Caesarean section are rigorously excluded. They state that they attach very considerable value to wide rupture of the membranes and now report a total series of 179 cases in which this was done nine out of ten were in primiparae and in one in five the os was closed, labour not having started. So far from the trauma provoking convulsions, it was found that in 60 per cent no fit occurred between artificial rupture of the membranes and delivery. In general, rupture, which is really a tearing of the membranes, is done (by removal of as much as possible of them by means of a vulsellum after dilatation to Hegar 20 or 22) when the general condition is grave (as in persistent albuminuria hypertension, or amaurosis), when the anti-toxaemic and narcotic measures have failed in the less severe cases or in recurrences. It is contraindicated and should if possible be replaced by Caesarean section when there is an abnormal presentation or prolapse of the cord. Its further adoption is said to be likely to improve greatly the prognosis in eclampsia.

435 Carcinoma of the Cervix

R SCHRÖDER (*Zbl Gynak* March 6, 1937, p 546) gives an account of treatment of carcinoma of the cervix and its results in a series of 604 cases (1922-30) in which a five year supervision was subsequently possible. Absolute cure in the sense of a five year survival in good health was obtained in 171 or 28 per cent. Increasingly good judgement in selection in the mode of treatment for particular cases together with increasing experience in all treatments, seemed to bring about an improvement in the results for the last three years (1928-30) 327 cases had 34 per cent of five year cures. For the whole period the operability rate was 58 per cent. The cases actually operated on totalled 50 per cent. Wertheim's operation was usually done in the first and Schauta's vaginal wide hysterectomy in the second half of the period under review. The primary mortality of the 178 Wertheim cases was 13 per cent., of the 124 Schauta cases 15 per cent. The Schauta cases had also a superior percentage of lasting cures—51 per cent., as compared with 36 per cent for the Wertheim cases. Radium treatment was given in 253 cases including fifty-one which were operable the mean dose was 2000 mg radium-element hours in fractional doses. In the operable cases this treatment led to a single death and lasting cures amounting to 42 per cent. In the inoperable cases (202) there was an 85 per cent primary mortality and 16.5 per cent of five-year survivals. (The recent radium mortality has been 4 per cent.) Considerable value in prevention of recurrences is ascribed to persistence with post-operative x-radiations in small dosage.

436 Ureteral Stricture in Dysmenorrhoea

NGAI MAN LEUNG (*Chin med J* March 1937 p 365) describes a case of stricture of the ureters in which the chief symptom was severe dysmenorrhoea. The case was treated by dilatation of the ureters once every two weeks for two months, and then on two other occasions. A complete cure was obtained. The author believes that this is a fairly common cause of dysmenorrhoea. The pain at the time of the menses is due to the premenstrual congestion superadded to the existing stricture. Cases of

dysmenorrhoea without obvious cause should be examined for signs of ureteral stricture.

Pathology

437 Iodine tolerance Test in Hyperthyroidism

H J PERKIN and F H LAHEY (*New Engl J Med* March 25, 1937 p 501) describe the results of 108 iodine tolerance tests. In a fasting state patients were given 6 minims of Lugol's solution by mouth, and 2 ccm of blood were taken for iodine analysis at periods of half an hour, one hour, one and a half hours and two and a half hours. Values of blood iodine in microgrammes per cent were plotted on a graph. Curves rising above 100 microgrammes per cent were regarded as normal. In general the blood iodine curve of a hyperthyroid patient did not rise to so high a level as in the normal individual. The authors believe that since hyperplastic thyroid tissue has an affinity for iodine, the differentiating principle of the test is dependent upon the presence or absence of hyperplasia. The test is of diagnostic value only in so far as hyperplasia of thyroid tissue is associated with clinical hyperthyroidism. Hyperplasia however, may be associated with myxoedema or found in patients without symptoms of hyperthyroidism. Conversely hyperthyroidism may exist without histopathological evidence of hyperplasia. Although not a specifically absolute test (in their cases the authors had a 20 per cent margin of error) estimation of the iodine tolerance is an aid to diagnosis when evaluated together with the clinical evidence.

438 Xanthoproteic Acid

F M CHIANCONE (*Biochim Terap Sper* February 28 1937, p 41) carried out experiments on white rats to determine the effect of pregnancy, age fasting and light on the formation of xanthoproteic acid and found that these conditions did not visibly modify its elimination. Oral administration of tryptophane was followed by the appearance of xanthoproteic acid in the urine as in the control animals. In all the cases relatively large quantities of tryptophane were needed before the xanthoproteic acid appeared in the urine.

439 Magnesium Tetany

S W HOOBLER, H D KRUSE and E V MCCOLLUM (*Amer J Hyg* January, 1937 p 86) have studied the changes in the total and ultrafilterable serum calcium and magnesium in magnesium tetany induced in four young dogs by feeding them on a magnesium-deficient diet. They found a moderate lowering of the total calcium level, to a mean value of 7.58 mg per 100 ccm with a disproportionately lesser decline (to a mean of 4.74 mg per 100 ccm) in the absolute values for the ultrafilterable fraction so that there was a slight increase in the proportion of the ultrafilterable calcium, together with a marked fall in the serum magnesium values (to mean values of 0.47 mg per 100 ccm for total and 0.35 mg per 100 ccm for ultrafilterable magnesium affecting both forms of magnesium alike so that their relation was unchanged. In addition there was a slight rise in the serum inorganic phosphorus. In the periods marked by convulsions the diffusible calcium levels in the serum were neither the lowest obtained nor so low as is usually associated with calcium tetany. On the other hand the values for diffusible magnesium were in or near what may be regarded as the critical range for magnesium tetany—that is below 0.4 mg per 100 ccm. The authors conclude therefore that not only by its symptomatology but also by its blood chemistry magnesium tetany may be differentiated from calcium tetany for changes in the serum calcium ion concentration appears to be unconnected with magnesium tetany which is however closely associated with extremely low concentrations of magnesium ions in the serum.

In the treatment of PERNICKIOUS ANÆMIA a 1937 achievement in chemistry

- 1 the purest Liver extract now available
- 2 $\frac{1}{10}$ th its former dry weight
- 3 painless on injection
- 4 monthly dry dosage is now similar to the dry dosage of Insulin required by an average diabetic case over the same period

G. L. AMPOULES

A full range of pure potent accurately standardised and sterile drugs is available in the special G.L. Ampoules which open with a clean break by means of a simple friction opener. Prices are lower than normal. Full list on request.

SOME PRODUCTS AVAILABLE IN G. L. AMPOULES

Calcium Levulinate G.L. (Levu-calcin) A sterile stable and completely non-irritant solution for urgent or intensive calcium therapy. Valuable in tetany, haemorrhagic states, pre-operative preparation. In 10% (intravenous) and 15% (intramuscular) solutions.

Iron Arsenic Strychnine Co. G.L. A valuable tonic for patients whose metabolic processes need prompt stimulation. Chlorbutyl incorporated and pH adjusted to ensure relatively painless intramuscular injection.

Thioisnamine-Ethyl-Iodide G.L. Combination of thioisnamine (ethyl-thio-urea) with ethyl iodide in aqueous solution containing 3 grains per cc. A well tolerated fibrolytic agent, valuable in local neuritis, fibrositis and rheumatic arthritis. Also in herpes zoster.

Manganese Butyrate G.L. A sterile 1% solution. Indicated in the treatment of staphylococcal infections e.g. boils, carbuncles, whitlow, abscess, erysipelas. For intramuscular injection.

INCREASED RATES OF BONUS ARE NOW ANNOUNCED BY THE MEDICAL SICKNESS SOCIETY

All members holding With Profit Sickness and Accident Policies or Life Assurance Policies share in the prosperity of this Mutual concern which deals exclusively with the Medical and Dental Professions. Non-members should apply for details of the Permanent Sickness Contract which gives benefits up to age 65 and substantial cash bonus at that age. Even with these advantages the premium is the cheapest obtainable.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF EXETER C.M.G., A.D.C.

Medical Superintendent DANIEL F. RAMBAUT M.A., M.D.

This registered Hospital is situated in 3.0 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra Violet Apparatus and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres. Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens and facilities are provided for handicrafts such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. ZUOZ COLLEGE, Near ST. MORITZ, UPPER ENGADINE

5680 FEET ABOVE SEA LEVEL

A HIGH-CLASS PUBLIC SCHOOL FOR BOYS IN THE ENGADINE

Conducted on English Public School lines with the Modern Language Features and Academic Advantages of Swiss Schools
Classical, Modern, Science, Commercial and English Sides Preparatory School

The lofty valley of the Upper Engadine occupies a unique position in Europe. It has a wonderful climate enjoying the advantages of an Alpine Climate at high altitude but under a southern sky. It has the maximum of sunshine and the minimum rainfall of the entire Alps. Thanks to the "inverted temperature" in has summer sunshine in winter.

"Asthma is almost unknown among the natives of the Engadine and similar centres in Switzerland and at least 90 per cent of asthmatics lose all or nearly all their symptoms within a very short period of their arrival in these places.

Residence for one year or preferably several years, in the Alps almost invariably leads to a permanent cure in children in spite of complete failure of every known form of treatment at home," from the *British Medical Journal* of November 9th, 1929 by Dr A F Hurst "The Pathogenesis and Treatment of Asthma"

Asthma cases are so free from the complaint that they can take a normal and active part in school life and games.

WE SPECIALISE IN POST-GRADUATE COACHING FOR ALL EXAMINATIONS

UNIVERSITY OF CAMBRIDGE

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY

The next course of study for the Diploma begins about October 5th 1937 and occupies about nine months. It comprises

(a) Four months instruction in Physics, Radiology and Pathology.

(b) Three months further instruction in Radiology and Electrology together with three months clinical work in the Radiological Department of a Hospital approved by the Managing Committee for the Diploma.

(c) Twelve months experience as clinical assistant in the Radiological Department of a Hospital approved by the Committee. Hospitals in London and the Provinces and Overseas have been approved for this part of the Course.

Examinations for Part I (Physics) will be held in February and July 1938 and for Part II (Radiology, Electrology and Pathology) in July and October 1938.

The University has decided that the Diploma shall cease to be granted after 1941. The last course for the Diploma will start in October, 1940 and the last examination will be held in October 1941.

The Course is open to men and women whose medical education is approved by the General Medical Council for purposes of registration and who satisfy the Committee that they have had sufficient practical experience.

The Secretary of State for the Colonies proposes to select within the next few months not less than 10 Medical Officers to fill vacancies the majority of which will occur in Tropical Africa or in Malaya

QUALIFICATIONS Candidates must be British subjects of European parentage, under 35 years of age and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases etc.

SALARY. Initial salaries vary from £600 to £700 and rise by increments to a maximum of between £1000 and £1200

PRIVATE PRACTICE Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions

QUARTERS In Tropical Africa free quarters, or an allowance in lieu are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary

PASSAGES Free first class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages

TERMS OF APPOINTMENT The appointments are pensionable subject to a probationary period which varies from two to three years

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE. Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas

DUTIES Although Medical Officers are appointed in the first instance for general service there are opportunities for work in special branches of medicine and surgery, in public health and in medical research

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S W 1

ROYAL NAVAL MEDICAL SERVICE.

A number of vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1937

Candidates must not be above the age of 28 years and must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000

At the end of five years Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post Graduate Study

Copies of the regulations for entry and conditions of Service including rates of pay and allowances may be obtained from the Medical Director General of the Navy, Admiralty, S W 1, and from the Deans of all Medical Schools

Applications for entry from intending candidates must be received not later than May 31st, 1937

COUNTY OF DORSET

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER and MEDICAL OFFICER OF HEALTH FOR THE PORTLAND URBAN DISTRICT

The Dorset County Council invite applications from Registered Medical Practitioners with at least three years experience since qualification and not exceeding 40 years of age for the joint appointment of Male Assistant Medical Officer for the Administrative County of Dorset and Medical Officer of Health for the Portland Urban District (population 12,000).

The salary for the combined appointment will be £500 per annum together with a travelling allowance of £50 per annum and necessary out-of-pocket expenses according to the scales now in force.

Experience in the treatment of venereal diseases as required by the Local Government (Qualifications of Medical Officers) Regulations 1930 and the possession of the Diploma in Public Health will be considered important additional qualifications.

The candidate appointed will as regards his duties as Assistant County Medical Officer act under the direction of the County Medical Officer of Health and will be required to perform such duties as may be from time to time prescribed. As regards his duties as Medical Officer of Health for Portland he will be subject to the control and direction of the Urban District Council.

The post will be designated under the Local Government and Other Officers Superannuation Act, 1922 and the successful candidate will be required to pass a medical examination. He will also be required to reside either in or in the vicinity of Portland.

Candidates must apply in their own hand writing on the prescribed form to be obtained on receipt of a stamped addressed foolscap envelope from the undersigned to whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than Saturday June 26th 1937.

Canvassing in any form will be a disqualification. County Offices, C P BRUTTON, Dorchester, Clerk of the County Council, May 21st 1937.

MINISTRY OF HEALTH

The Minister of Health invites applications from registered medical practitioners (men and women) for vacant appointments as MEDICAL OFFICERS on the STAFF OF THE MINISTRY.

The salary commences at £847 per annum and rises by annual increments of £30 to a maximum of £1,161 per annum.

The appointments will be subject to the usual Civil Service conditions as to pension holidays etc.

Candidates must be registered medical practitioners of not less than five years standing and have experience in Public Health or Hospital services.

Generally preference will be given to candidates possessing a University degree in Medicine and a Diploma of Public Health but for one of the appointments special surgical experience of the treatment of Cancer by modern methods would be taken into consideration.

Medical Officers are required to devote their whole time to the Public Service and must be prepared to work in any part of England or Wales if required to do so.

Canvassing through Members of Parliament or in other ways will render a candidate liable to disqualification.

Forms of application with further particulars of the appointments may be obtained from — THE DIRECTOR OF ESTABLISHMENTS, Ministry of Health.

Whitehall S.W.1. No application can be considered unless received on the prescribed form not later than June 8th 1937.

COUNTY BOROUGH OF BLACKBURN

Applications are invited from registered medical practitioners for the post of ASSISTANT SCHOOL MEDICAL OFFICER and ASSISTANT MEDICAL OFFICER OF HEALTH (Male) to act under the supervision of the Medical Officer of Health who is also the School Medical Officer.

The person appointed must devote the whole of his time to the service of the Corporation.

The duties of the office will consist largely but not exclusively of work in the School Medical Department and a knowledge of such duties is essential. Preference will be given to candidates with a Diploma in Public Health and having experience in infectious diseases.

The salary will be at the rate of £600 per annum (increasing by annual increments of £25 to a maximum of £700 per annum).

Forms of application and further particulars of the duties and conditions of the appointment may be obtained from the Medical Officer of Health, Victoria Street, Blackburn.

Canvassed by a copy of the three recent testimonials, must reach me by FRIDAY, June 18th and should be endorsed on the envelope "A vacant School Medical Officer". Can anyone will disqualify.

Town Hall, CHAS S ROBINSON, Blackburn, J. A. BROWN, J. A. BROWN, J. A. BROWN.

COUNTY OF DORSET

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER

The Dorset County Council invite applications from registered medical practitioners with at least three years experience since qualification not exceeding 40 years of age for the appointment of Male Assistant County Medical Officer.

Salary £500 per annum rising (subject to satisfactory service) to £700 by annual increments of £25 together with travelling and out-of-pocket expenses according to the County Scale.

Experience in the treatment of venereal diseases, as required by the Local Government (Qualifications of Medical Officers) Regulations 1930 and the possession of the Diploma in Public Health will be considered important additional qualifications.

The candidate appointed will be required to reside at Dorchester to devote his whole time to the service of the County to act under the direction of the County Medical Officer and to perform such duties in connection with the County Council's Health Services as may be allotted to him.

The post is designated under the Local Government and Other Officers Superannuation Act, 1922 and the successful candidate will be required to pass a medical examination.

Candidates must apply in their own handwriting on the prescribed form to be obtained on receipt of a stamped addressed foolscap envelope from the undersigned to whom applications accompanied by copies of not more than three recent testimonials must be received not later than Saturday June 26th 1937.

Canvassing in any form will be a disqualification. County Offices, C P BRUTTON, Dorchester, Clerk of the County Council, May 13th 1937.

CITY OF COVENTRY

ASSISTANT MEDICAL OFFICER (woman)

Applications are invited from duly qualified and registered women medical practitioners under 40 years of age for the post of Assistant Medical Officer in the City of Coventry Public Health Department. The duties will be mainly in connection with the maternity and child welfare scheme. Preference will be given to candidates possessing a Diploma in Public Health.

The salary will be £500 per annum rising by annual increments of £25 to a maximum of £700. The officer appointed will be required to devote her whole time to the duties of the post.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act 1922 and the successful candidate will be required to pass the necessary medical examination as to fitness and to contribute to the Superannuation Fund.

Applications, together with copies of three recent testimonials must be made on the prescribed form (which may be obtained on request) and must reach the undersigned on or before June 2nd 1937. The Council House, A MASSEY, Coventry, Medical Officer of Health, May 14th 1937.

BELLERGAL

THE REGULATOR OF AUTONOMIC FUNCTION

"In the treatment of autonomic dystonia it is necessary to consider the simultaneous influence of an associated sympathetic and vagus excitation Rothlin has shown that a combination of Bellafoline and Femergin is well suited as a sedative of the autonomic nervous system, particularly as regards peripheral hypertonicity The addition of phenobarbital, a sedative of the central nervous system, to this combination gives the preparation known as Bellergal which is now established as the remedy of choice for the treatment of autonomic dystonia"

MARTELL

THE FILTER TIP WILL KEEP THEM FIT

Because of its double function, the "du Maurier" filter tip has become a really important factor to smokers—specially to those with a tendency to sensitive throat. Each "du Maurier" has a five layer filter made up of pure white vegetable tissue interleaved with cellulose fibre. The filter allows no bits in the mouth and isolates all irritants. This filter is a feature on both the plain tip 'medium' and the cork tip.

MODERN AIDS TO HEARING

These announcements are intended to illustrate the latest advances in acoustic science in order that the medical profession may be kept informed of the newest aids available for the deaf

"Electro-Ear"

Micro telephone wearable aid comprising only two parts a very small earpiece and the transmitter case. A small battery is housed inside the case and this new design embodies a combined slider switch and volume control conveniently placed. It is a very helpful aid for most cases of middle ear deafness and can be worn easily and inconspicuously for business or home use.

JOHN BELL & CROYDEN

Acoustic Department,

WIGMORE STREET, LONDON, W.1.

A copy of our new booklet describing all types of aids will gladly be sent on request

The service with facilities for testing and comparing almost every make of aid with individual assistance in each case

DESOUTTER

CASE RECORDS

Case No 2159/1472. 1935

Miss A, a hospital patient, aged 25 years, was sent to us in April, 1935. She had had both legs amputated below the knee eight years previously as a result of septicemia following an accident. Owing to general ill-health and lack of funds she had not been fitted with limbs but for seven years had managed to get about the house on her knees, causing deep-seated callouses to develop. See Figure 1. Apart from these callouses she had a good 7 in left stump which was easily fitted with the normal below-knee limb. The right stump, on the other hand, was extremely short, only 1½ in of tibia being left, and it appeared on first sight that the patient would have

to be fitted with a kneeling appliance. However, on examination, it was found that as the leg had been amputated immediately below the tibio-fibula joint there was an exceptionally large bone surface which made it possible to use the end of the stump as a weight bearing point, and with the remanent of calf muscle being used to obtain a retaining grip, a normal below-knee type limb was fitted with only a slightly longer thigh corset to give additional lateral support. Although this is without doubt the shortest stump to which it is possible to fit a below-knee limb the patient has good control over both limbs and walks well with natural knee actions.

IN THE PAST 6 MONTHS 35 HOSPITALS HAVE TESTED
AND APPROVED OF THE **BAXTER "VACOLITER"**
THEY FIND THIS SERVICE
UNIFORM • SAFE • ECONOMICAL

PROVED.

Before a single litre of Baxter's solutions was sold to the profession generally there was a history of five years of research plus two years of development, then three years of successful clinical use by a selected group of hospitals. We could not afford to guess — nor can you Baxter's solutions in Vacoliters are always sterile ready to use and instantly available. We have been able to prove to many hospitals that they bring the advantages of safety and improved service at reduced cost.

TESTED

Solutions in Vacoliter dispensers are prepared from a fractionated protein-free water. Their pH value is always consistent with their concentration. Baxter solutions are stable and sealed in vacuum and sterilized under recorded control. Each time a new solution is made up it is biologically tested. We ask you to give them a thorough clinical test. What you find out for yourself will be more eloquent than any claims we could possibly make.

No longer need patients suffer pain whilst undergoing minor operations bone setting etc. Enquiries are invited for an illustrated booklet describing the Queen Charlotte's Gas Air Analgesia machine. This apparatus provides a safe, economical, portable compact and simply operated Gas-Air machine which, during a year's test at Queen Charlotte's Hospital has proved satisfactory in every way.

QUEEN CHARLOTTE'S APPARATUS

Consider the advantages of an individually designed **SPENCER** **MATERNITY SUPPORT**

Exact fit, gentle support and restful comfort are assured because each Spencer Support is individually designed, cut and made from exact measurements and posture description of the patient. This is to be expected.

Every Spencer is designed to improve posture, provide abdominal support and place the pull of support on the pelvic girdle, not on the spine or above, the lumbar region. (Supports which place the strain on the spine or, above, the lumbar region, tend to cause backache.)

Backache when due to lumbo-sacral or sacro-lumbar strain, faulty posture or any other condition which creates abnormal tension in the muscles of the back is definitely relieved by a Spencer. Furthermore its combination of abdominal and back support provides a restful comfort that has a favourable effect on the patient's state of mind. Nausea when not strictly pathological, relieved by the wearing of a Spencer.

Spencer Supports are individually designed for: Pre-eclampsia, Heart, Sacro-lumbar Strain, Intero-phosis and Intestinal Secretion, Kidney, Pregnancy and Parturition Support.

Spencer supports gain patients' co-operation because they are accepted, applied principles and fine style lines. They improve appearance, are lightweight, flexible, easily laundered and are guaranteed to keep their shape.

Spencer Maternity Corset. The only corset that gives support to the abdomen and back.

Spencer Supports and Corsets are now sold in shops.

OVALTINE

IN NUTRITIONAL CRISES

WHILE the average adult is able to maintain a healthy existence on the ordinary everyday diet, there are certain periods in the life of each individual when an increased demand for the vital food elements arises. Outstanding examples are the period of adolescence, the pregnant and nursing states and the stage of convalescence after severe and lowering illnesses.

Ovaltine is an eminently satisfactory adjunct to the ordinary dietary at all such times. Composed of fresh full-cream milk, eggs and malt extract in proportions adjusted to meet physiological requirements it provides in an agreeable form calcium, phosphorus, vitamins and other important food elements.

Ovaltine is a metabolic stimulant and digestive which assists the assimilation of other foods and promotes general good health. It can, therefore, be taken regularly with advantage in place of tea, coffee or other beverages. A noteworthy feature is its delightful taste which is appreciated by people of all ages.

Mild Constipation shown to yield to laxative effect of HOVIS

Many of the mild forms of constipation so prevalent to-day are attributed to the consumption of foods deficient in Vitamin B'. In comparing the effects of various kinds of bread it is seen that HOVIS germ bread is superior to either white bread or wholemeal in supplying this deficiency. Whilst white bread contains practically no Vitamin B', HOVIS, with its added

proportion of 25% wheat-germ, supplies an abundance of this essential food element. Unlike wholemeal bread, HOVIS contains only a minute percent age of bran and indigestible cellulose. In other words its incorporation in the normal diet ensures not only a higher standard of nutrition but easier assimilation and regular evacuation of the intestinal contents.

THE IDEAL ANTACID

Magnoleum is an emulsion of liquid paraffin and magnesium hydroxide prepared entirely by mechanical means without the aid of any constipating mucilaginous emulsifying agents. Its action is that of its active ingredients in an extremely fine state of sub-division. Being perfectly

miscible with water or milk it may be diluted before taking given to bottle-fed infants in food, etc. It is readily acceptable to children and delicate or fastidious adults. Issued in convenient wide mouthed glass bottles 1/3 and 2/6. Write for specimen for clinical trial.

'ZYMINE' Peptonising Tubes (FAIRCHILD)

For the preparation of Peptonised Milk and other Predigested Food for the Sick

'Zymine' Peptonising Tubes have been in use since 1882, making it possible for physicians to assure proper nutrition to their patients, even in cases where digestive power has been reduced to its lowest terms, and enabling chronic dyspeptics, invalids, convalescents, etc., who must live upon fluid foods for more or less prolonged periods to take milk in quantities sufficient to maintain nutrition and promote restoration

PEPTONISED MILK presents all the nourishment of plain milk freed from the objectionable qualities which constitute so serious a drawback to the utilisation of milk in the feeding of the sick. And of the many methods employed to make milk an available food for the sick, there is none that approaches the 'Fairchild' peptonising process in the certainty with which it accomplishes the desired purpose

Supplied in boxes containing 6 and 12 Tubes

The contents of one Tube will peptonise one pint of Milk

INFANTILE ECZEMA.

A quick cure—'would usually take months'
writes doctor

The doctor's letter

I happened to have in my consulting room a baby with eczema of the scalp which would normally have taken months to cure

I tried it with Sphaenol Ointment with most satisfactory results and am so pleased with the preparation that I should be grateful if you would forward me a parcel of it

Yours truly
M.B.

Reports of speedy cures with Sphaenol Ointment are not uncommon but the great virtue of Sphaenol Ointment is this—that from the first touch it is soothing cooling. Used against eczema Sphaenol brings sure relief from itching and at the same time its healing peat principle helps the growth of clear healthy skin

Perhaps you have had no personal experience of Sphaenol. Then the makers will gladly send you free samples

RADIOSTOLEUM

(Standardised Vitamins A and D)

A valuable prophylactic in pregnancy

Radiostoleum fortifies the body's first line of defence against the inroads of infective organisms by building up its power to promote epithelial integrity, its administration is indicated, therefore, during the last few months of pregnancy in order to build up the mother's resistance against infection at the birth, and, furthermore, to counteract, on account

of its Vitamin D content, a deficiency of this calcifying vitamin. Moreover, the administration of Radiostoleum ensures an abundance of the two vitamins, A and D, to meet the needs of the growing foetus, a shortage during that particular period of development producing in some cases almost irreparable defects in after life.

MANDELIX

(Elixir of Ammonium Mandelate B.D.H.)

IN URINARY TRACT INFECTIONS

During the last twelve months Mandelix has established itself as the medicament of choice in the treatment of urinary infections by reason of the advantages which it possesses over other forms of mandelic acid treatment. For example, patients appreciate the acceptable flavour of Mandelix and show no antipathy to the treatment as was the case with the earlier preparations of mandelic

acid, further, in the majority of cases supplementary administration of ammonium chloride—also a product with an objectionable flavour—is unnecessary, the urine being maintained at the right degree of acidity by the administration of Mandelix alone. As a result of Mandelix therapy a sterile urine is produced usually within a week even in cases with a chronic infection.

INSULIN 'A.B.'

Insulin 'A.B.' was the first British insulin offered commercially to the medical profession. Its manufacture on an industrial scale was the direct result of research carried out by the joint manufacturers in their physiological and chemical laboratories, its supremacy has been fully maintained by the persistent work of the research staff engaged in its production.

Insulin 'A.B.' has a world wide reputation for its strictly safeguarded sterility, its carefully standardised strength, its freedom from toxic reactions and its stability in hot climates.

Proved efficiency with pleasantness

In spite of its high germicidal efficiency (Ridcal Walker 30) 'Dettol' can be used at strengths impracticable with carbolic and cresylic antiseptics. It is non poisonous, non staining, pleasant smelling. It has been shown that when 30% 'Dettol' is rubbed into the hands and allowed to dry the skin remains insusceptible to infection by haemolytic streptococci for at least two hours, unless grossly contaminated. 'Dettol' is also stable in the presence of blood, pus, faeces and other organic matter.

Obtainable from chemists in 1/- and 3/- bottles and in larger sizes for medical and hospital use. These prices do not apply in the Irish Free State and Overseas. Samples and full information on request.

FORMULA

Uralsol, In addition to being a solvent and eliminator of pathological Uric Acid is a powerful urinary antiseptic

Normally the excretion in the body of a certain quantity of uric acid, which is gradually absorbed and after it has played its part is eliminated together with the normal thymine acid of the organism. When, however, uric acid is present in excess, the body needs additional thymine acid to supplement the normal deficiency of this essential element of uric acid.

Uralsol, By its thymine acid component, it acts as the agent for the elimination of uric acid.

The result is that the uric acid is eliminated from the body and the normal thymine acid is restored.

Uralsol, By its thymine acid component, it acts as the agent for the elimination of uric acid.

Catarrhal Infections

In private practice the physician is often conscious that, despite his efforts, the patient does not progress, even in convalescence, to a better state of general health. Lowered vitality is often the reason for such a condition. In such cases a roborant is needed, and Sanatogen, which is a *chemical combination* of ninety-five per cent concentrated milk casein and five per cent sodium glycerophosphate, offers the ideal prescription.

"I have used Sanatogen extensively in my private practice with gratifying results. I have found it very beneficial in a boy of 7 years of age, who was susceptible to catarrhal infections. I have found that Sanatogen has increased his resistance to these conditions, and that he is in very much better health generally."—M.B., B Ch.

ROBINSON'S BARLEY WATER

KEEN ROBINSON & CO., LTD. Catrow Works, Norwich

Heat Sterilized without loss of flexibility

Surgical Catgut is manufactured from the submucous cellular coat of the sheep's intestine

This material is converted into gelatin by the action of heat in the presence of moisture.

Heat sterilization is carried out therefore, after complete dehydration of the catgut. After sterilization, the tubes of catgut are filled with a 96% alcoholic solution, the 4% aqueous content imparting flexibility to the suture.

This variety of catgut, as taken from the tube, has the correct degree of flexibility and tensile strength. The suture requires no conditioning before use.

The entire product manufactured in England.

Descriptive booklet will be sent on application.

TOP—Removal of the mucous coat by mechanical means, before decomposition commences.

BOTTOM—Hermetically sealing glass tubes containing sterile catgut.

EXAMEN

REGD TRADE MARK

HIGHEST POTENCY

No other commercial liver extract is so highly concentrated as Examen. The haemopoietic factor derived from 100 grams of fresh liver is contained in an average of only 10-15 mgms per 2 cc. ampoule.

GREATEST PURITY

Examen is twice to forty times as pure as any other liver extract. Its remarkably low total solid content represents a minimum amount of inert matter.

PROVEN UNIFORMITY

The introduction of Examen was intentionally delayed for many months until extensive clinical trials proved its high potency and purity to be constant and completely dependable.

RATIONAL DOSAGE

The dosage scheme for Examen is based, not on dramatically favourable nor even on "average" responses, but on amounts known by continued clinical tests to be more than sufficient in treatment and maintenance of pernicious anaemia.

ADVANTAGES TO PATIENT

Examen is painless on injection and produces no allergic reactions. Moreover, dosage is relatively infrequent and thus the administration of Examen is at no time a physical or financial burden.

CLINICAL CONFIRMATION

Every new batch of Examen is subjected to clinical trial before being released, providing practical assurance to the physician that he may always rely upon the purity and potent haematinic effect of his individual supply.

A booklet fully describing the evolution, practical advantages and dosage of Examen is available to the medical profession on application to — Glaxo Laboratories Ltd. (Write to J. Middlemass)

EARLY DIAGNOSIS AND TREATMENT OF HEART FAILURE*

BY

WILLIAM EVANS, M.D., F.R.C.P. LOND

Assistant Physician London Hospital

(WITH SPECIAL PLATE)

Few illnesses can more readily compel a medical attendant to apply immediate therapeutic measures than heart failure. So alarming may be the symptoms and so great the anxiety surrounding the patient that a demand for hurried action is everywhere evident. Never is the necessity greater, however, for the doctor to make haste slowly, to act promptly but not precipitately, and yet again to treat cautiously but expeditiously. The need to do something is always present, but it should be no greater than the need to know everything before doing anything, so that an immediate perception of the expected course of the illness, and the processes involved, is an essential preliminary to the competent treatment of heart failure.

The Mechanism of Heart Failure

Although the true mechanism of heart failure continues to remain an unsolved problem, our knowledge of it on the one hand has helped us to conceive certain principles in treatment, and on the other hand our lack of knowledge is unlikely to have withheld anything revolutionary from present-day methods of dealing with the condition. The changes during failure are familiar to us, it is the evolution of these changes which eludes precise exposition.

The back pressure failure theory envisages stasis of blood in the vascular areas which drain in the direction of the affected heart chamber, so that obstruction in the mitral valve is expected to produce the following sequence of changes: distension of the left auricle, engorgement of the lungs, distension of the right ventricle and of the right auricle, engorgement of the veins of the neck and cyanosis, distension of the liver, and oedema of the lower extremities. Recently it has been shown (Thompson and White 1936) that left ventricular strain from hypertension, aortic valve disease or infarction of the left ventricle is the commonest cause of hypertrophy of the right ventricle, which occurs regardless of the presence of clinical evidence of left ventricular failure although this increases the degree of hypertrophy.

The forward pressure failure theory, supported by Sir James Mackenzie, postulates systemic failure following inadequate output of the left ventricle, while pulmonary symptoms in the same way are the outcome of failure of the right ventricle. This deficiency in the outflow of blood results in a depletion of the vascular areas and in ischaemia of the tissues situated in front of the affected heart chamber.

It is likely that both back pressure phenomena and a diminished cardiac output are features that exist together in many if not in most instances of congestive heart failure, but the knowledge of the part which each plays

in the development of failure is unlikely to contribute in a greater measure to the treatment of the condition than to indicate the need of relieving congestion and of increasing the efficiency of cardiac contraction.

Size and Position of the Heart in Failure

Cardiac enlargement is usual in failure, but it is rarely the direct result of failure, and its distribution and extent depend chiefly on the lesion which is providing the cause of the failure. Either with or without failure the progression of cardiac enlargement is very gradual so that sudden dilatation of the heart seldom occurs. Whenever such an event has been implied from a clinical examination, and displacement of the apex beat to the left has been noticed, three influences contriving to produce this change must be kept in mind before attributing it to cardiac enlargement. They are tachycardia, distension of the liver and ascites producing elevation of the diaphragm, and a right-sided hydrothorax. Even on radioscopic caution must be exercised when assessing the development of cardiac enlargement, so that the "squatting" posture of the heart, assumed as a result of a raised diaphragm from any cause, must not be interpreted as enlargement. Again, the possibility of pericardial effusion enlarging the cardiac silhouette as seen on radioscopic should receive attention in any case where an exacerbation of failure signs has occurred with the formation of effusion within serous cavities.

It is held by some that hydrothorax (usually right-sided) from heart failure does not cause cardiac displacement,

FIG A.—Displacement of heart in failure. Diagram showing superimposed outline of heart in teleradiographs 1 and 2 of the Special Plate.

but this is fallacious (see Figs 1 and 2 on Plate and Fig A in text). Certainly it does not displace the heart to the same extent as does an inflammatory pleural effusion because the quantity of fluid is not so great and, further, whenever the effusion in heart failure has become considerable pulmonary congestion with pleural effusion

*The substance of a lecture delivered before the North Eastern and Big Knoll Division of the British Medical Association, March 16, 1937.

occurs on the opposite side, and this opposes the initial displacement

Evidence of Early Failure

The need for recognizing early heart failure is only equalled by the need for early treatment and early treatment depends on early diagnosis. In order to gain this end the earliest evidence of failure must be sought in those patients known to suffer from heart disease which is expected to give rise to heart failure sooner or later. In them symptoms develop gradually and almost imperceptibly, so that our awareness of this happening will usually lead us to seek for premonitory signs and not to wait for the fully developed clinical picture of heart failure characterized by cyanosis, considerable breathlessness, conspicuous engorgement of the veins of the neck, pulmonary congestion with right-sided hydrothorax, enlargement of the liver with ascites, oedema of the lower extremities, and scanty urine with albuminuria. The recognition of early congestive heart failure depends on attention to the following essentials: undue breathlessness to customary exertion, venous engorgement, pulmonary congestion, hepatic distension, and a familiarity with the causes of heart failure.

Undue Breathlessness

Breathlessness on exertion occurs in health. With advancing age or with the onset of obesity this natural reaction to increased physical performance becomes accentuated. The breathlessness which heralds the commencement of heart failure is characterized by its occurrence during exercise which hitherto produced no breathlessness, or which is in excess of that measure which was customarily induced by a standard form of exercise. Thus the hall-mark of pathological breathlessness is present when exercise which usually produced no breathlessness induces it, when exercise which previously initiated breathlessness causes undue breathlessness, and when the breathlessness has shown progression within a relatively short period of time.

Venous Engorgement

An increase in the venous blood pressure may be regarded technically as the first evidence of heart failure but unfortunately its estimation cannot be carried out with the same ease as the registration of the arterial blood pressure. The direct method of recording the venous pressure by connecting a venepuncture needle to a manometer filled with citrate solution cannot for obvious reasons become common practice in clinical medicine so that some other means denoting a change in the venous pressure is desirable. Sir Thomas Lewis (1930) directed attention to a method which permits an approximate clinical estimate of the venous pressure. He pointed out that in health all veins which lie at a higher level than the manubrium sterni remain collapsed and those below are distended. Thus in a healthy patient in the reclining posture with the head resting on a pillow the external jugular veins are distended for about one third their course from the clavicle to the angle of the lower jaw. In a patient presenting a slightly raised venous pressure the column of venous distension reaches the centre of the sternomastoid muscle or higher. The veins in the neck are not evident in a healthy subject in the erect position but in established heart failure they are visible as cords reaching from the clavicle to within a variable distance of the mandible. This clinical indicator of the venous pressure should gain significance not only on account of its relative accuracy but also on account of the simplicity of the observation.

Pulmonary Congestion

When persistent crepitations are elicited over the bases of the lungs, mostly on the right side, from heart failure, the presence of a considerable degree of pulmonary congestion can be presumed. Earlier evidence of pulmonary engorgement is marked by vascular congestion in the hilum of the lungs. Careful auscultation along each side of the spine over the middle zones will often disclose, especially after coughing, isolated coarse crepitations at the end of a deep inspiration, but commonly the presence of this degree of congestion can only be made out on radioscopy, certainly the extent of hilar congestion can only be told by this method. The picture obtained is a characteristic one presenting wing-like shadows spreading from each hilum, and caused by an increase in the density of the pulmonary vessels, which are depicted here and there in cross section and appear like ink blots (Plate, Figs 3 and 4).

The help provided by radioscopy in the recognition of early heart failure has not yet gained the reputation it deserves. Nor should the method be applied solely in diagnosis, for it also provides an index in the evaluation of progress during treatment, so that the extent of hilar congestion as determined at intervals by radioscopy determines the advance or retreat of the process of failure (Plate, Figs 3 and 4).

Hepatic Distension

An increase in the volume of the liver is a sensitive indicator of an increase in the venous blood pressure. Although this natural manometer does not supply accurate quantitative values, when enlargement of the liver has been made out it serves as early evidence of heart failure, so that whenever failure is suspected or expected distension of the liver should be sought. Palpation immediately below the right costal margin may elicit tenderness in a patient presenting hepatic distension, but a quest for the descended liver edge as the hand travels upwards from a low position is a more reliable method of examination.

Specific Causes of Heart Failure

Familiarity with the conditions capable of precipitating heart failure ensures timely and efficient attention to a patient in whom failure threatens. To anticipate heart failure is often to postpone it to remain unaware of its causes and its early manifestations is to allow its grosser signs to develop. The causes of heart failure may be conveniently considered in two groups, as suggested by Parkinson and Clark Kennedy (1926), but here a reference to these will only include in the first place any special features which facilitate early diagnosis and secondly those details concerning the treatment of each group which cannot be regarded as common to all cases of failure.

Treatment of Established Heart Failure

Certain general principles apply to the treatment of most of the common examples of heart failure, so that in the first place it is opportune to consider these and later to detail any particular remedy or procedure which may apply when certain specific causes are present. An outline of those therapeutic measures to be adopted in the general case of heart failure is facilitated by referring to three distinct clinical types—established heart failure, early heart failure and abrupt heart failure.

The designation "established heart failure" is applicable when a patient presents characteristic physical signs of failure which have developed gradually and have pro-

gressed during the absence of treatment or with inadequate treatment. No rigid rules can be formulated to govern the management of all cases of established heart failure, but although every patient must be studied individually the treatment should generally provide for adequate rest, digitalization, and diuresis.

REST

In ambulatory cases a limitation of activity is of first importance in treatment, and in order to gain the fullest benefit from this curtailment of exercise the patient's usual daily habits should be ascertained and a programme modifying the day's activities should be complete in detail. A later rising time in the morning and an earlier retiring time at night periods of rest in the reclining posture after meals, walking slowly on level ground and avoiding hurrying and climbing, are among the instructions imparted to the patient in whom established heart failure is controlled by digitalis medication. At night the provision of extra pillows promotes rest and sleep.

In non ambulatory cases absolute rest is sought, and a patient is discouraged from indulging in any exertion, not even turning in bed. Again the head and shoulders should be supported in the upright posture, and although devices to meet this necessity have been improvised in the form of chairs, extension of these amenities to the construction of special beds has received but scant attention. Such a bed was designed by Sir Thomas Lewis, but the adoption of this helpful instrument in the treatment of heart failure in the wards of a hospital has proceeded very slowly.

Inseparable from any method adopted to ensure rest in a case of heart failure is the alleviation of the patient's natural apprehension and the provision of sleep. Alcohol, in that it is conducive to sleep and causes a feeling of well being may be dispensed with benefit, but in no sense must it be regarded as a heart stimulant. A mixture containing 20 grains of potassium bromide and chloral hydrate often suffices as a hypnotic or resort may be made to the barbiturates (sodium luminal 1 to 2 grains) or morphine (1/2 grain dissolved in the mouth, or 1/4 grain hypodermically). Certainly these drugs should be used with determination as they are important agents in the treatment of heart failure.

DIGITALIS

Good wine needs no bush and certainly the utility of digitalis in the treatment of heart failure does not need to be advertised; it has proved its worth. What does require emphasis is that it should be used in adequate doses so that our duty in treating heart failure is not so much the giving of digitalis as establishing a state of digitalization. Digitalization is only present when the patient's symptoms are lessened when diuresis has resulted when the pulse rate has been slowed to 70 per minute or under, when the ventricular rate has been similarly diminished and the pulse deficit annulled and when depression of the R-T segment is a feature of the electrocardiogram.

A choice of the preparation of digitalis must necessarily be made before determining the dosage. It is most desirable to adhere to the administration of a single preparation and acquire experience of its effects in different patients. Nothing is gained in fact a good deal is lost by substituting various preparations of digitalis either in the same patient or in different patients. It is far better to acquire exact knowledge of the value of a single preparation than to nourish a doubt concerning the comparative value of a number of preparations. The following may be regarded as representative of the digitalis group

and dependable when used in the indicated daily doses powdered leaf (4 grains), tincture (45 minims), Nativelle's granules (1/125 grain), and digoxin tablets (0.45 mg). Although these doses are comparable and basic they are not to be regarded as absolute standards in all patients with established heart failure. The dosage should be adjusted according to the severity of the failure, weight of the patient, and particularly the length of time required to establish a state of digitalization. In most instances the suggested standard dose is the approximate one, but often it will need increasing and sometimes decreasing.

DIURESIS

To produce efficient diuresis should be a constant aim in every case of established heart failure, and there is more than one method available to attain this object.

That rest in bed combined with a diminished fluid intake can produce prominent diuresis has not gained sufficient recognition. Fig B illustrates this effect in a

FIG B—Chart showing diuresis following rest in bed and a diminished fluid intake in a patient with mitral stenosis and heart failure with normal rhythm.

female, aged 36 years, with mitral stenosis, in whom the features of early heart failure presented. Cognizance of this happening is necessary in the evaluation of any remedy credited with diuretic properties in the patient instanced here unmerited repute might have been accorded any drug professing a diuretic action if it had been introduced when the patient was voiding scanty urine on admission to hospital. The lesson in this connexion is twofold: first it impresses the need of prescribing rest combined with a diminished fluid intake (1½ pints daily) in patients presenting heart failure, and, secondly, it emphasizes the importance of adequately controlling all clinical tests conducted to assess the diuretic properties of any drug.

Foremost among the drugs which can effect diuresis in heart failure when administered by mouth, is digitalis, and in most instances it should be preferred to other remedies in this group, such as ammonium chloride or the purine diuretics—for example, theobromine diuretin, theophylline or euphylline.

Intravenous and intramuscular salyrgan or novurit in 2 c.cm doses are pre-eminently the most powerful diuretics we possess and they form important implements now available to combat the effects of heart failure and to help restore cardiac efficiency. Parkinson and Thomson (1936) have shown that novurit gives satisfactory results when used as a suppository although of course its diuresis is not so profuse as when it is introduced intravenously.

or intramuscularly, but the advantages afforded by the simplicity of this method of administration are obvious. The prescribing of ammonium chloride along with salyrgan increases diuresis, but this is not always considerable. The most recent advancement in the treatment of heart failure has been the addition of mercurial diuretics to the other effective therapeutic agents—rest, digitalis, and hypnotics.

The effect of total ablation of the thyroid gland in heart disease presenting paroxysmal nocturnal dyspnoea and heart failure has to be discussed. Impressions concerning the benefit gained from this procedure are best got from a study of the results obtained in seventy-eight cases [thirty six by Blumgart and others (1935), and forty-two by Levine and Eppinger (1935)]. The therapeutic benefit enjoyed by some of these patients coincided with the lowering of the basal metabolism, and when this became reduced to minus 30 per cent. myxoedema frequently intervened, and this in turn responded to small doses of thyroid without materially detracting from the improvement resulting from the lowering of the basal metabolism. If heart failure was present with persistent oedema the operative risk increased considerably, so that it is evident that *total thyroidectomy is not often desirable* in instances showing failure, and certainly this procedure should be undertaken only when the recognized methods of treatment have failed and when the operation can hold out a reasonable prospect of considerable improvement.

Treatment of Early Heart Failure

A patient with heart disease is commonly examined during the pre failure period, when he will derive greater benefit from observation and instruction than from the initiation of any form of zealous treatment. Medicinal treatment, apart from a placebo, is unlikely to produce material benefit during this period. Certainly any attempt at digitalization at this stage is ill advised and without promise of improvement, so that it should be discouraged even though it might be given without harm.

In particular the patient is to be instructed on the subject of activities and diet. While it is permissible or even desirable to indulge in limited or graduated exercise, exertion is prohibited. In connexion with diet it is desirable that it should not be heavily salted and stress is directed to two main essentials—namely the avoiding of large or indigestible meals and, if obesity is a feature the resorting to a fat-reducing diet.

To gain the co-operation of the patient during this pre-failure phase should be a first consideration. No amount of enthusiasm or even heroism in treatment will produce improvement if the patient is not the doctor's ally. Nor must the psychological side be neglected so that encouragement and just optimism should be dispensed along with firm dissuasion where needed. The over-cautious should receive encouragement, and the reckless should be restrained and be made to realize the consequences of any disregard to instructions. Improved health should be promised on conditions and as a reward of attention to advice.

If the signs of early heart failure are beginning to collect and there is increased breathlessness, slight venous engorgement in the neck, and hilar congestion detected by radioscopy apart from the precautions already enumerated concerning exercise and diet, periods of controlled rest should be outlined. These will be in the mornings and evenings after the midday meal and at the week-ends. Digitalis should be added if auricular fibrillation has set in. The administration of mercurial diuretics combined

with a much-reduced fluid intake should be conjoined with the week-end rest.

The treatment adopted for this group of patients almost merits the designation prophylactic treatment, at any rate, it aims at postponing the signs of established heart failure. The measure of success gained from the care devoted to these cases justifies the zeal involved in collecting cases within the scope of this group.

Treatment of Abrupt Heart Failure

In some patients in this class the precipitation of heart failure may be an unforeseen contingency, and this particularly applies to cardiac infarction. It may also occur unexpectedly in hypertension, although paroxysmal nocturnal dyspnoea will often serve as a premonitory sign. Sudden exacerbation of failure symptoms may also occur in cases with established heart failure hitherto controlled by treatment, or even in some instances of early failure, in both of these groups either a period of increased activity and exertion or some intercurrent illness has caused a damaged heart to fail suddenly.

It is in this class of cases that the urge to do something is so strong and good judgement so often yields to mismanagement created by over-enthusiasm. The term 'cardiac stimulant' designates the drug whose purpose it is to help the heart in this sudden crisis. Many drugs have gained a reputation in this field, but usually this has not been merited and has been gained through uncontrolled clinical impressions. Strychnine, camphor, and pituitary are in this category, and have far survived their usefulness in this connexion. A warning is overdue concerning the danger of the wholesale and indiscriminate use of proprietary preparations imputed to be of this class of 'cardiac stimulants' in virtue of their action, variably claimed to be on the medulla, on the peripheral circulation, on the coronary circulation or as 'cardiac hormones'. A plea for resort to controlled clinical assay is made in order to regain a proper perspective of the value of these potions.

Strophanthin has seldom shown superiority over digitalis in cases of precipitate heart failure. Digitalis, particularly digoxin, has great value in abrupt heart failure associated with auricular fibrillation. Oral administration of 1 mg. of digoxin can lower the ventricular rate in auricular fibrillation within a few hours. Its success when the heart rhythm is regular is not so assured. Little or no advantage is gained by intravenous administration of digitalis.

Whenever cyanosis is a prominent feature and there is conspicuous venous engorgement in the neck, venesection is good practice. If restlessness and sleeplessness present hypnotics must be administered in adequate doses after providing support for the head and shoulders and making the patient comfortable.

If oedema and ascites are features salyrgan is indicated. In the case of a female patient with much oedema it is necessary to anticipate the considerable diuresis by tying in a urinary catheter in position so that the patient's energy is in this way conserved. Salyrgan medication has dispensed with the necessity of purging an oedematous patient for the purpose of ridding him of superfluous tissue fluids.

Heart Failure in Specific Conditions

Certain special features in the mechanism of early diagnosis and treatment of specific conditions which intimate failure will now be described.

HYPERPIESIA

Whenever congestive heart failure appears in a patient and the heart rhythm is regular, hyperpiesia may be regarded as the likely cause. To bear this in mind is to recognize the underlying condition when the failure has produced a fall in the blood pressure value. Sometimes when the onset of failure has caused the systolic figure to fall to a normal level the diastolic value has continued to remain high, permitting the diagnosis of hypertension. Often however, a fall in the diastolic blood pressure has accompanied a similar change in the systolic blood-pressure value and the diagnosis then rests on a record of a raised blood pressure during the pre-failure period and the finding of cardiac hypertrophy chiefly involving the left ventricle. An ominous sign has appeared when heart failure has been added in a case of hyperpiesia. Improvement may occur for a time, but longevity can hardly be mentioned in connexion with prognosis.

Digitalis is without any great reputation in the treatment of hypertensive heart failure, but it always merits a trial in individual cases, as it will usually produce some degree of improvement. Certainly it is the treatment of choice in the less common instances where auricular fibrillation is present.

The mercurial diuretics salyrgan and novurit hold first place in the treatment of hypertensive heart failure, and the administration of these should be augmented by providing organized periods of rest and a diminished intake of fluid (Figs 5 and 6).

Further, when failure has set in as a complication of hypertension, paroxysmal nocturnal dyspnoea (cardiac asthma) is a frequent accompaniment, and demands specific treatment in addition to the general regime adopted for the failure. The patient must be propped up in bed and potent hypnotics such as sodium luminal, 14 grains or morphine 1/4 grain administered each night until the general condition is improved from the use of diuretics. Digitalis medication should also be given a trial in these cases.

AORTIC INCOMPETENCE AND AORTIC STENOSIS

Aortic incompetence from syphilitic aortitis and endocarditis invariably precipitates heart failure with a regular cardiac rhythm and so does rheumatic aortic incompetence if the mitral valve has remained healthy or is only slightly damaged. Similarly the cardiac action is regular in aortic stenosis with heart failure if the aortic valve is the only valve affected. As in the case of hyperpiesia the onset of failure is a serious complication, and signals a grave outlook.

The failure associated with aortic valve disease also assumes hypertensive failure in that digitalis assumes second place to salyrgan or novurit, except in the less frequent instances where failure has recurred with auricular fibrillation.

CARDIAC INFARCTION

Although arrhythmia especially auricular fibrillation is sometimes present in cardiac infarction in the majority of cases normal rhythm is preserved. The signs of failure may appear abruptly in this condition and if the area of infarction is a large one the signs are correspondingly increased, thus pulmonary congestion becomes prominent, and not infrequently crepitations are found scattered over both lungs. The liver too may become distended early in the illness, and slight oedema of the ankles may appear.

Treatment of the failure in this instance resolves itself into dealing with cardiac infarction, so that rest ensured by morphine is the procedure to adopt in patients in this group.

CONGENITAL CARDIOVASCULAR DISEASE

Heart failure is not a common feature of congenital cardiovascular disease, and pulmonary infection and sub-acute bacteraemic endocarditis are the more likely complications to ensue. Cyanosis in these cases usually only serves to indicate the presence of a venous-arterial shunt, and is seldom an expression of the presence of heart failure. In those instances of congenital cardiovascular defects where cyanosis appears later in life the onset of heart failure may have caused cyanosis by producing a reversal of an existing arterio venous shunt into a venous-arterial shunt. The symptoms of dyspnoea and cyanosis, therefore, in congenital heart disease are not commonly manifestations of congestive heart failure, they do not call for special care or treatment except in those few instances which show frank signs of failure.

The cardiac rhythm continues to be regular after failure has set in unless congenital heart-block is present as a rare feature of interventricular septum defect. When failure has set in it is usually progressive, although adequate rest and treatment with mercurial diuretics and digitalis may produce temporary improvement.

EMPHYSEMA AND BRONCHITIS

Too often in the past a patient giving a history of a productive cough occurring mostly during winter months and presenting great breathlessness, cyanosis, and abundant adventitious sounds in the chest, has been regarded as a case of heart failure. More notice should be taken of emphysema as a common cause of extreme breathlessness and less of its influence on the heart. The severe breathlessness associated with emphysema is the direct result of a diminished pulmonary ventilation, and is only rarely the sequence of heart failure. The effects of emphysema on the heart have recently received attention. Parkinson and Hoyle (1937) determined the size and shape of the heart by radiology in eighty patients suffering from a high grade of emphysema. Enlargement of the pulmonary artery stem and its branches and of the conus of the right ventricle was present in about one half of the cases. Changes due to hypertension were also commonly met with. About one third showed no cardiac enlargement. Heart failure was infrequent (thirteen out of eighty) and in seven of the thirteen cases hypertension was a feature. They stated that congestive failure purely from emphysema and chronic bronchitis was rare and had a grave prognosis so that recurrent failure was almost unknown.

Of even greater importance in the management of a case of heart failure is the recognition of the effects of emphysema and chronic bronchitis in a patient presenting heart disease. The occurrence in these cases of attacks of acute bronchitis produces an exacerbation of symptoms and may cause alarm, for the breathlessness may be extreme and accompanied by a distressing cough with the voiding of thin sputum and often haemoptysis. In the presence of mitral stenosis and auricular fibrillation such symptoms have been attributed too readily to heart failure and the added pulmonary signs have been erroneously assigned to pulmonary congestion from failure instead of to diffuse bronchitis and emphysema. The treatment of each condition is so dissimilar as to urge the necessity

of recognizing in many cases of heart disease this prevalent "bronchitic element," and of deciding its influence in producing the symptoms before treatment is commenced. Adrenaline or ephedrine and a mixture containing potassium iodide, stramonium, and ammonium carbonate prove more beneficial than an increase in the dose of digitalis. It is likely, from experience with this type of case, that certain proprietary adrenaline like preparations have gained an over-measure of trust in the treatment of all cases of heart failure.

NEPHRITIS

Heart failure is a common event in nephritis when hypertension is present. In chronic nephritis cardiac asthma is often an added feature. This frequent occurrence of heart failure in nephritic hypertension is not universally realized, particularly in hypertension of acute nephritis. Ellis (*personal communication*) found evidence of heart failure in twenty instances among 100 patients with acute nephritis, and in nine of these it was severe. The importance of a more general acceptance of the common incidence of heart failure in nephritic hypertension is found in a wider application of specific remedies in these cases to cardiac rather than to renal failure.

ADHERENT PERICARDIUM

Adhesions may form between the parietal and visceral layers of the pericardium, partially or completely obliterating the sac, and yet produce no cardiac embarrassment nor result in cardiac enlargement unless valvular disease is present. In another group calcification of the pericardium may be added, but without symptoms. Where extrapericardial adhesions have bound the heart to the surrounding structures (mediastino-pericarditis) cardiac enlargement is often present, but even here coincident valvular disease may account for the enlargement. A special feature of a fourth group is the constriction of the superior and inferior venae cavae, and to a less extent the heart, by adhesive pericarditis, giving rise to a characteristic clinical syndrome (Pick's syndrome). The effects of these changes is to produce a condition comparable to that of heart failure but without pulmonary congestion, so that the symptom of breathlessness is never prominent in the initial stages. The means of recognizing cases in this group has been clearly detailed by Paul White (1935), who refers to the leading clues in the diagnosis in the following order: The insidious onset of dropsy and oedema of the lower extremities in a young person. Preponderant enlargement of the liver with ascites. Undue prominence of the jugular veins with increase of the venous pressure. Absence of any heart disease or nephritis in a case presenting dropsy. Small and regular pulse with a low systolic blood pressure and pulse pressure. Evidence of chronic pleurisy. Calcification of the pericardium seen on radiology. Low voltage curve in the electrocardiogram with flattening or inversion of the T wave in one or more leads. Previous history of pericarditis and polyserositis.

Pericardial resection by an experienced thoracic surgeon is the only method of treatment which holds promise of recovery from the effects of constrictive pericarditis and the number of patients who have gained benefit from this surgical procedure is fast increasing.

ARTERIO-VEINOS ANEURYSM

When a small communication has been established between an artery and a vein there is no demonstrable change in either the anatomy or function of the heart but

if the fistulous opening is a large one then symptoms and signs of heart failure develop. It is the arterio-venous aneurysm resulting from trauma therefore and situated in the extremities, particularly the thigh and leg, which specially produces changes in the heart. Here breathlessness and palpitation are common symptoms, and considerable enlargement of the heart, especially the left ventricle, is demonstrable on radiology. The pulse is regular, a little rapid, and is collapsing in character with an increase of the pulse pressure, obliteration of the arterio-venous shunt by digital compression raises the systolic and particularly the diastolic blood pressure, and the collapsing nature of the pulse disappears, the pulse rate also falls abruptly. With the fistula open the venous blood pressure is increased and pulmonary congestion is visible on radiology. Extirpation of the aneurysm causes the cardiac enlargement and the pulmonary congestion to disappear within a short period of time (see Figs 7 and 8), thus providing a rare example of reversible cardiac enlargement.

MITRAL STENOSIS

Most instances of mitral stenosis showing evidence of heart failure present arrhythmia, usually in the form of auricular fibrillation, but occasionally as auricular flutter, in some the rhythm remains regular. It is likely that early indications of heart failure are invariably present before the onset of fibrillation, and that the adoption of efficient treatment during this pre-fibrillation period postpones the onset of fibrillation. Once auricular fibrillation has become established in a case of mitral stenosis digitalis is pre-eminently the medicine to prescribe. In the uncommon instances of mitral stenosis presenting prominent and aneurysmal dilatation of the left auricle the absence of gross heart failure symptoms may be a notable feature.

THYROTOXICOSIS

Slight cardiac enlargement occurs commonly in patients with thyrotoxicosis in the absence of auricular fibrillation and heart failure, but failure is seldom if ever present with a normal cardiac rhythm. Again, not all cases of thyrotoxic fibrillation show evidence of failure. When it has set in digitalis will produce some improvement but subtotal thyroidectomy after adequate treatment with Lugol's iodine is unquestionably the proper course to adopt. An attempt to re-establish normal rhythm by quinidine administration during the pre-operative period is of doubtful value.

COMPLETE HEART BLOCK

When complete heart block is complicated by heart failure and when Adams Stokes attacks are absent digitalis is worthy of trial because it often produces clinical improvement and the failure symptoms disappear without causing undue slowing of the pulse. In cases subject to Adams Stokes attacks digitalis is contraindicated as it usually increases the incidence of the attacks.

Conclusion

In conclusion it may be said that in the diagnosis and prevention of heart failure it is important to seek early evidence of this in patients presenting heart disease which can ultimately precipitate failure and that in treatment it is necessary to individualize to treat with determination but not over-zealously to prescribe remedies whose worth has been established by repeated and controlled clinical trial to gain the full co-operation of the patient and to give constant encouragement.

LUPUS VULGARIS

TREATMENT BY INTRADERMAL INJECTION OF
HYDNOCARPATES

BY

J. EDGAR WALLACE, M.D.,

Assistant Tuberculosis Officer West Sussex County Council
late of Lancashire County Council

(WITH SPECIAL PLATE)

The numerous methods which have been devised for the treatment of lupus vulgaris bear adequate testimony to the obstinate nature of this disease. For this reason the encouraging results that have recently been obtained by the intradermal injection of esters of hydnoctarpus oil deserve more widespread attention than they have as yet received. Leprosy workers have for some years made increasing use of this method in dealing with cutaneous lesions and the analogy between this disease and tuberculosis led to the account by Sir Leonard Rogers (1933) of a case of extensive lupus vulgaris successfully treated in this way.

Soon after this publication treatment was commenced in the present series of fifteen cases, and preliminary reports were issued in the succeeding two years (Wallace, 1934 and 1935). More recently Burgess (1935) has described a series of eleven cases, in which clinical cure was obtained in seven and improvement in the remaining four.

Choice of Preparation

The substance first used in the present investigation was that known as moogrol. This is prepared by esterizing the total acids of hydnoctarpus oil, and consists of ethyl hydnoctarlate and ethyl chaulmoograte together with the esters of the other acids present in this oil. As reactions were sometimes unduly severe iodized moogrol (containing 0.5 per cent of iodine) was also tried. This however, seemed less efficacious and in addition produced in the skin a bluish brown discoloration of considerable persistence.

Later at the suggestion of Dr T. A. Henry of the Wellcome Chemical Research Laboratories both these forms were abandoned in favour of a third preparation phenyl ethyl hydnoctarlate. The change proved to be a satisfactory one as reactions became much less marked, and treatment could thus be advanced more rapidly. Phenyl ethyl hydnoctarlate which is therefore the preparation of choice is now on the market under the trade name of eulskol (Burroughs Wellcome and Co.). Its less irritant effect has been made possible by eliminating the small unsaturable portion of the total fatty acids during the preparation of the ester.

Technique

Injections are made intradermally with an ordinary 1 c.c.m. hypodermic syringe fitted with an agla 240 needle

(B.W. and Co.) This is a 3 mm needle fitted with a guarded point. Patients attend weekly, and at each sitting a series of wheals 1/2 cm to 1 cm in diameter are raised in the lupus patches and nodules. The total amount of injection at any one time has not exceeded 1 c.c.m., but Burgess, using phenyl-ethyl hydnoctarlate exclusively, has injected as much as 5 c.c.m. Reactions can be diminished by spacing the wheals as far apart as possible, and no area should be injected a second time until all inflammatory changes have subsided.

Lastly, it is important to avoid subcutaneous injection. This not only causes more severe diffuse reactions but also fails to produce the desired effect, for, as Beatty (1932) points out, the lupoid foci are mostly in the corium, and there is a layer of corial connective tissue between them and the subcutaneous tissue. These precautions are particularly to be observed in lesions around the eyes, where swelling of the loose tissues may be greater than elsewhere, and may cause some concern to the patient.

Effect of Injections

No general disturbance of any sort has been noted. The injection itself is practically painless but during the next forty eight hours a certain amount of redness and swelling appears, accompanied by a slight degree of pain and tenderness. The pain lasts for one or two days only, but the swelling may not subside for a week or longer.

As treatment continues a slowly progressive flattening of nodules and plaques occurs, together with a disappearance of scales and crusts. The granulation tissue between the lupoid areas diminishes. Tiny ulcers may appear in and around the site of injection. A varying degree of redness prevails, but gradually the active lesions are replaced by pale smooth scar tissue. Several months may elapse after the cessation of treatment before the final effect is seen. During this time the tendency to relapse is no less apparent than in other forms of lupus treatment. Careful observation is necessary to ensure that any recurrent nodules can be reinjected at the earliest possible moment.

The esters of hydnoctarpus oil are absorbed very slowly from the skin, and their effect on lupoid tissue is continued long after the purely irritant reaction has worn off. For this reason one hesitates to regard the action entirely as a non specific one, unless it be due, as Muir (1932) suggests, to the liberation of antigens.

Summary of Cases

The fifteen cases summarized in Tables I and II all attended a tuberculosis dispensary of the Lancashire County Council. Previous treatment had consisted of local and general artificial light therapy and occasional spiking with acid nitrate of mercury, but the lesions had mostly reached that curiously resistant stage where the disease appears to be neither advancing nor healing. All other forms of treatment were stopped at the commencement of the new method so that a fair trial could be made.

The length of treatment has varied in individual cases from six months to three years although in the longer cases as the condition improved injections have frequently been spaced out at fortnightly or even monthly intervals. Treatment has been unduly prolonged in some cases since considerable caution was exercised at the onset owing to the experimental nature of the method.

Progress has undoubtedly been more rapid than that made by artificial light treatment alone but there is no reason why eulskol injections should not be supplemented by general carbon arc baths as in some of the cases.

TABLE I—*Lupus Vulgaris Treated with Intradermal Injections of Hydnocarpates (15 Cases)*

Case	Age	Site of Disease	Duration of Disease in Years	Length of Treatment	*Approximate Size of Active Areas in Square Centimetres		Condition at Present Date
					Before	After	
1	35	Neck	10	9 months	27	Nil	Quiescent (see Plate)
2	29	Elbow	14	3 years	—	Nil	Quiescent (see Plate)
3	35	Forehead and forearm	24	3 "	—	—	Much improved
4	48	Forearm	40	3 "	25	3	Quiescent except for few nodules
5	18	Arm	10	6 months	—	Nil	Quiescent
6	27	Face and neck	13	2½ years	17	Nil	Quiescent
7	12	Thigh	2	9 months	9	Nil	Quiescent
8	14	Face	10	10 "	—	Nil	Quiescent
9	39	Face and neck	25	12 "	—	—	Slight improvement. Ceased treatment
10	14	Thigh	3	11 "	25	Nil	Quiescent (see Plate)
11	24	Neck and wrist	23	2½ years	36	20	Much improved wrist quiescent. Ceased treatment

† Three cases were abandoned for reasons unconnected with the treatment. Two of these (Cases 11 and 14) are included in the "much improved" group, the other (Case 9) in the "slight improvement only" group.

reported by Burgess. Reactions too, are definitely less painful than those resulting from the usual caustic applications.

The cost is trivial, and the technique is so simple that the time factor at each session is reduced to a minimum. Patients as a whole have expressed satisfaction with the treatment and have attended with great regularity—a point of no little significance.

The intradermal injection of hydnocarpates in the small number of cases so far available has produced extremely encouraging results and appears to offer certain advantages over other routine methods. Further clinical trials are awaited with interest and some degree of confidence.

I have to express my thanks to Sir Leonard Rogers and to Dr T. A. Henry for their helpful interest. I am also indebted to Dr G. Lissant Cox, central tuberculosis officer, and to Dr E. H. A. Park, consultant tuberculosis officer, both of the Lancashire County Council, for permission to publish these findings.

IDIOPATHIC STEATORRHOEA

REPORT OF A CASE ARISING IN ADULT LIFE

BY

A. M. NUSSBRECHER, M.D., M.R.C.P.

Physician to Selly Oak Hospital, Birmingham

AND

F. MORTON, B.Sc., A.I.C.

Biochemist to the Hospital

It is largely due to the work of Hess Thaysen that attention has recently been drawn to persistent diarrhoea found in adults in non-tropical countries. This condition has variously been called idiopathic steatorrhoea, non-tropical sprue, and 'Gee-Thaysen's disease'. Following Hess Thaysen's observations (1929) several important series of cases have been collected (Holmes and Starr, 1929; Bennett, Hunter, and Vaughan, 1932; Thaysen, 1935; Moore *et al.* 1936), whilst isolated instances, some of which bring new and interesting points to light, have also been recorded (Mackie, 1933; Fullerton and Innes, 1936). In the majority of the cases described the symptoms apparently originated in childhood, the diarrhoea and tetany recurring in adult life with intermediate periods of remission. In many of these instances there was evidence of rickets, infantilism, and gross bony deformities. Bennett, Hunter, and Vaughan (1932) concluded from their observations that the spontaneous occurrence of the disease in adult life, though not impossible, would be very rare. The later studies of Hess Thaysen (1935) have shown that onset of symptoms in adult life is not so infrequent as was formerly believed. The same author has stipulated as criteria of the disease the following four points: (1) an abnormally large quantity of fat excreted in the faeces; (2) a normal or in some instances a slightly increased nitrogen excretion; (3) a flat blood sugar curve; and (4) a raised basal metabolic rate. Our own case conforms with the first three of these points, and reveals several other interesting features which make it worth recording.

Case Record

Clinical History.—The patient, a female 40 years of age, was quite well until seven years ago when fourteen days after her last confinement she began to have "dysentery". She counted as many as twenty motions a day (an average of about fifteen) and frequently had to get up at night for bowel actions. She noticed the stools were offensive, greyish white in colour, frothy and occasionally slimy but never blood stained. She had been feeling weak and cold for a considerable time and since May 1936 had experienced cramps in the hands and feet and occasionally in the abdomen. These cramps occurred mostly on exertion and also appeared to be precipitated by the menstrual periods. While they were present the fingers were drawn into the palms. Her feet and legs had swollen especially after she had been up for some time, and her face had also swollen occasionally. She had lost weight from 10 st. 12 lb. three years ago to a present average of 8 st. Her periods have been regular but the actual loss only slight.

The patient first came to our notice on August 14, 1936, when she was admitted to Selly Oak Hospital in an actual attack of tetany. Her condition then was as follows: Fairly well covered, colour good, no pigmentation, teeth in good condition. Slight oedema present over feet and lower parts of legs. Carpo-pedal spasm present. Trouseau's and Chvostek's signs positive. Marked hyperexcitability of all muscles including those of the tongue. Slight glossitis present. Heart and lungs normal. Blood pressure 120/80. Abdomen was distended and rectum somewhat ballooned. The urinal showed no abnormality.

Progress and Investigations—For the first week after admission the number of stools (putty-coloured and offensive) averaged about five a day but later dropped to one a day. Ammonium chloride 30 grains t.d.s. by mouth, was sufficient to check the tetany in about forty-eight hours.

On August 17 1936 the serum calcium was 6.8 mg. and the plasma phosphorus 2.9 mg. per 100 c.cm. On August 22 the red cells numbered 4,840,000 per c.mm. the haemoglobin percentage was 86 and the colour index 0.9. There was slight anisocytosis and the average size of the red cells was 7.5 microns. Examination of the faeces showed no occult blood. The total fats comprised 34 per cent of the dried material, the neutral fat was 4.8, the free fatty acids 15.2 and the soaps 14.1 per cent. On August 19 calcium lactate 30 grains three times a day was started by mouth. On the 25th the serum calcium was 8.1 mg. and on the 29th 8.2 mg per 100 c.cm.

A fractional test meal showed achlorhydria. X-ray examination of the tibia with control showed no decalcification and a barium enema demonstrated a marked dilatation of the colon.

The patient was discharged on completion of these investigations at her own request.

SECOND ADMISSION

She was readmitted on November 17 1936 with the following history. After leaving hospital she remained well only for about a week when the diarrhoea returned (about eight stools per day). Spasms in limbs returned also but with greater severity. Between the major spasms she had the sensation as if something were creeping under the skin all over the body.

On readmission she was in severe carpo pedal spasm which necessitated immediate injection of 20 c.cm. calcium laevulate intravenously. She was then given ammonium chloride 30 grains t.d.s. and calcium lactate 40 grains four hourly but without apparent effect. The spasm returned on the 20th when the serum calcium stood at 6.3 mg per 100 c.cm. and the plasma phosphorus at 1.5 mg. Another 20 c.cm. of calcium laevulate intravenously brought relief but though further 10-c.cm. injections were given on the 21st and 22nd a severe spasm occurred on the 23rd which was countered with a further dose of 20 c.cm. calcium laevulate. Ten units of parathormone on the 24th did not prevent another spasm on the following day this being again relieved by intravenous calcium laevulate. Just prior to this attack the serum calcium stood at 6.2 and the plasma phosphorus at 2.2 mg. per 100 c.cm. Six further injections of 10 units of parathormone were given on alternate days but they had no immediate marked effect on the level of the serum calcium which on the 27th was still 6.2 mg., and on the day after the last injection of parathormone (December 7) rose only to 7.2 mg per 100 c.cm. Her general condition was however very much improved and although all administration of calcium was discontinued from December 8 the serum calcium rose to 8.4 mg. on the 16th.

A slight oedema of the legs persisted during this period in hospital in spite of complete rest in bed whilst occasionally her face was puffy. This oedema was found to be associated with consistently low serum protein values as the following figures show.

21/11/36	Total serum protein	4.9 grammes per 100 c.cm.
27/11/36	" "	5.0 "
8/12/36	" "	5.1 "
16/12/36	" "	4.6 "
Albumin 1.4 grammes globulin 1.5 grammes.		

The following investigations were also carried out during the second period of admission.

Glucose Tolerance Test—Fasting blood sugar 63 mg per 100 c.cm. After 30 grammes by mouth 1½ hour 68 mg. 1 hour 76 mg. 1½ hours 88 mg. 2 hours 88 mg. 2½ hours 88 mg.

Fat Metabolism—Fats minus 5 per cent of statistical normal (F.Q. 0.85).

Renal Function Test

	Urea Concentration		Time
	Vol	Urine urea	
Before urea	60 c.cm.	0.84 %	60 min
1st hour after urea	188 c.cm.	0.65 %	60 min
2nd " "	86 c.cm.	2.34 %	60 min
3rd " "	33 c.cm.	2.85 %	30 min
Blood urea before urea by mouth during first hour 19 mg per 100 c.cm.			
Standard urea clearance 82 per cent of normal value (van Slyke).			
Blood urea during second hour after urea 58 mg per 100 c.cm.			
Standard urea clearance 89 per cent of normal value			

Calcium and Phosphorus Balance—The calcium intake during the three-day period was 0.54 gramme. The calcium output during the three-day period was in urine 0.058 gramme and in faeces 0.761 gramme giving a total of 0.819 gramme. The phosphorus intake during the three-day period was 1.341 gramme. The phosphorus output during the three-day period was in urine 0.862 gramme, and in faeces 0.865 gramme giving a total of 1.727 grammes.

Daily Fat Excretion—On a diet containing 39 grammes of fat per day a twenty-four hour specimen of faeces contained 13 grammes total fat. The same dried stool contained neutral fat, 9.3 per cent, free fatty acids, 19.7 per cent, soaps 22 per cent.

Blood Examination—The red cells numbered 4,960,000 per c.mm. and the haemoglobin percentage was 96. The blood cholesterol amounted to 136 mg. per 100 c.cm.

The urine indican reaction was strongly positive.

X-ray examination of long bones with control again showed no evidence of decalcification.

We are indebted to Mr Philip Jameson Evans of the Birmingham and Midland Eye Hospital who kindly carried out a slit lamp examination and found two circular opacities in the left lens.

THIRD ADMISSION

The patient was discharged on December 18 1936 on a low fat diet adequate calcium hydrochloric acid and vitamin D but this did not prevent a recurrence of tetany, which necessitated readmission for the third time on January 7 1937. Intravenous calcium was needed as before to check the spasms. During this admission we took the opportunity of confirming our previous findings on daily fat excretion together with an investigation of the nature and origin of the excreted fat. The nitrogen balance was also determined whilst the patient was stabilized on a fixed diet (carbohydrate 114, fat 39, protein 31 grammes). The results of these investigations were as follows. Of the 39 grammes of fat in this diet 35.6 grammes consisted of butter the characteristics of which were saponification value 231 and iodine value (of the free fatty acids) 32.7. The total fat excreted per day amounted to 14.7 grammes and this had the following characteristics: saponification value 208, iodine value (of the free fatty acids) 19.6.

Nitrogen Balance—Intake during two days was 9.8 grammes. The urinary output 11.5 grammes and the faecal output 0.5 gramme, giving a total of 12 grammes. The negative balance, therefore was 1.1 grammes per day.

Blood examination showed 4,000,000 red cells per c.mm., and 76 per cent. haemoglobin.

Blood sugar curve—10 grammes of glucose were administered in the form of a 5 per cent. solution intravenously over a period of fifteen minutes. The fasting blood sugar was 95 mg. per 100 c.cm., ten minutes after the injection was completed it was 140 mg., half an hour later 90 mg. and one hour later 90 mg. per 100 c.cm.

Discussion

Careful inquiry into the history of our case disclosed no evidence of diarrhoea or tetany prior to the onset of the present condition at the age of 34. This instance therefore supports Hess Thaysen's postulate that there is no reason why idiopathic steatorrhoea should not arise in

adult life in non tropical countries. In common with the majority of cases already described our patient presents a persistent fatty diarrhoea, low serum calcium and phosphorus, actual or latent tetany, a flat blood-sugar curve after glucose ingestion, marked dilatation of the colon, and abdominal distension. She also shows achlorhydria and a moderate degree of glossitis, but no evidence of any marked anaemia.

In view of the recurrent tetany and the constantly low serum calcium, one would expect some evidence of skeletal decalcification, but the absence of this may perhaps be explained by the results of the calcium balance, which point to only a small loss of endogenous calcium. The nitrogen balance determination eliminates any possibility of the steatorrhoea being of pancreatic origin. Hess Thaysen has stressed the necessity of this investigation in the differential diagnosis of pancreatic and idiopathic steatorrhoea. Together with the urea concentration test the faecal nitrogen value indicates that, in contrast with the faulty absorption of fats and possibly of carbohydrates, nitrogenous products are efficiently absorbed by the patient. Under the existing circumstances one would look for some increase in the nitrogen metabolism, and it is probable that the loss of weight and the low serum protein value with its associated oedema are evidence of protein malnutrition, resulting not from any disturbance in digestion or absorption, but from a relative insufficiency of protein intake.

The interpretation of the results of the inquiry into the nature of the faecal fat is admittedly difficult, owing to lack of published data. The character of the excreted fat differs considerably from that of the ingested butter, indicating that total faecal fat measurements cannot be regarded as a quantitative index of the absorptive power of the intestine towards fats. The fact that the iodine value of the faecal fat is lower than that of the ingested butter is suggestive of its being derived from the food and not from endogenous fat, the iodine value of which is much higher. This would support the usually accepted theory that the steatorrhoea in such cases is due to deficiency in intestinal absorption rather than to the alternative possibility of derangement in the mechanism of excretion from blood into the intestine.

Treatment of our patient has been disappointing. In spite of adequate doses of calcium, vitamin D, hydrochloric acid by mouth and a low fat diet relapses continue to occur, and it appears that the only measure which checks the diarrhoea effectively is complete rest in bed.

Summary

1. A case of idiopathic steatorrhoea originating in adult life is described.
2. A surprisingly good general condition of the patient and absence of bone decalcification in spite of persistently low serum calcium are noted.
3. Evidence is brought forward showing that absorption of fat and carbohydrate is inefficient, while that of protein is normal.
4. Persistent oedema associated with low serum protein is observed and an explanation for this is suggested.

THE CULTIVATION OF MYCO. TUBERCULOSIS FROM HUMAN SPUTA

BY

J F D SHREWSBURY, M D, D P H.

AND

J BARSON

(From the Bacteriological Department University of Birmingham)

The routine laboratory examination of sputum from suspect cases of pulmonary tuberculosis consists of the microscopical examination of appropriately stained films of the sputum. This is the only method recognized by the tuberculosis authorities for which they accept the financial responsibility. Every laboratory worker knows that it is only of use in positive cases and that a negative microscopical report on a single sample of sputum is of no diagnostic value. It is interesting to compare the reliance placed on the microscopical method in tuberculosis to the present position in regard to the laboratory diagnosis of diphtheria, yet there is no valid reason why cultural examination of sputum and other morbid materials for *Mycobacterium tuberculosis* should not be practised as a routine procedure and be recognized as equal in value to the cultivation of *C. diphtheriae* from throat swabs, etc. Given a reasonably simple and effective technique, the examination can be incorporated in the ordinary routine work of the laboratory, *Mycobacterium tuberculosis* is not a difficult organism to cultivate, though it is a slow grower even under optimum conditions.

We have tested the following technique over the past two years and have found it suitable for the routine cultural examination of sputum. Before incorporating the method in our routine work we carried out a large number of control cultivations on morbid materials in which *Mycobacterium tuberculosis* was found by microscopical examination. This method yielded 100 per cent positive cultural isolations from tuberculous sputum, cerebro spinal fluid, faeces, urine, and pus. Having thus established to our satisfaction the value of the method we then proceeded to apply it to the examination of a series of sputa that were negative for *Mycobacterium tuberculosis* on microscopical examination.

Technique

Any volume of sputum up to a maximum of about 5 ccm is thoroughly mixed with an equal volume of 4 per cent caustic soda solution. The mixture is incubated at 37° C for thirty minutes and is then centrifuged—in our case for one hour at 3,000 r.p.m. (The speed and time of centrifugation can probably be safely varied to suit individual convenience so long as the entire quantity of particulate matter is firmly packed at the bottom of the tube.) The supernatant fluid is then carefully decanted and the deposit rendered neutral to litmus with 4 per cent hydrochloric acid. As a rule about five drops of acid are required to neutralize the deposit from an initial volume of 5 ccm of sputum. The deposit is then thoroughly mixed up with a sterile glass rod and is thickly sown on to the selected medium.

Three media have been tested in the course of our work—namely Löwenstein's, Petroff's and Petraganis's—employing the method of preparation described by Jamieson (1936). All three media have given successful results, but we have found Löwenstein's to be the best for routine use. In our experience different strains of *Mycobacterium tuberculosis* have varied in their preference for these media.

all the strains we have isolated have grown readily on Lowenstein's medium. The way in which the medium is used appears however, to be a determining factor in the cultivation of the bacillus in some cases at least. Medium slanted in test tubes is generally unsatisfactory, and has often given no growth when parallel cultures put up in screw-capped bottles as recommended by McCartney (1934), have shown good growth. We therefore strongly advocate the routine use of these bottles as containers for the selected medium. The cultures are of course incubated at 37° C. Growth is usually visible in twenty-one days but even when no colonies are visible at the expiration of this period there may be a good growth of *Mycobacterium tuberculosis* as an extremely thin film on the surface of the medium. No cultures should therefore be discarded as negative until they have been examined microscopically since transplants from these film growths grow vigorously and typically.

In our series of negative microscopical sputa examined culturally we have included only those which contained purulent matter purely mucoid and salivary specimens were not considered. Up to the present we have examined 135 specimens from which we have cultivated acid-fast bacilli—with the morphological and cultural characters of *Mycobacterium tuberculosis*—in twenty-nine cases (21.4 per cent). Most of these cultures have not yet been subjected to the biological test, but two of them have been inoculated into guinea pigs because their extreme chromogenicity gave rise to some doubt about their identity. In both cases the inoculated animals showed the characteristic picture of experimental tuberculosis when they were killed and typical acid fast bacilli were found in film preparations from the affected lymphatic glands.

Results of the Investigation

From the above findings it is evident that in 21 per cent of cases the ordinary routine laboratory test for pulmonary tuberculosis failed to give information that is of vital importance both to the individual and to the community. Tubercle bacilli can only be discovered with certainty by microscopical examination when they are present in large numbers in the sputum, but cultivation can detect them when they exist in very small numbers. In the early stages of pulmonary tuberculosis the bacillus will only be found in small numbers in the sputum. These are just the cases in which a positive laboratory diagnosis is of the greatest value and which are most likely to be missed by a purely microscopical examination.

The positive cultural findings in most of our twenty-nine isolations were accepted by those who submitted the specimens to us as agreeing with or confirming their clinical findings. In three cases however we were informed that there was no clinical evidence of phthisis, and that the cultural findings could not be accepted. We were not informed why in the complete absence of any suspicion of phthisis the sputum should nevertheless be sent to the laboratory for examination for *Mycobacterium tuberculosis* but probably the examination was requested as a precaution for the relatives. Assuming that in these three cases the clinical opinion is correct and that no tubercle bacilli exist in the sputum, the isolation of the bacilli from the sputum raises the very interesting problem of the bacillus being either temporary or permanent. Cases of *Mycobacterium tuberculosis* certainly exist, and in some instances with a high degree of acquired resistance to the tubercle bacillus, but the relation between the clinical and cultural detection of tuberculosis is a problem which has to be known to help

as the microscopical test is accepted as the routine procedure by the tuberculosis authorities. The institution of a routine cultural examination of all purulent sputa that are microscopically negative would, we believe, throw light upon this important problem and lead to the recognition of those early cases in which there is some hope of permanent cure by efficient treatment.

The Fermentative Reactions

An additional feature of our study has been an examination of the sugar fermentation reactions of *Mycobacterium tuberculosis*. Our investigations are at present not far advanced, but as they may be of some value to workers interested in systematic bacteriology, and as the pressure of routine work makes it extremely unlikely that we shall be able to complete them in the near future, we include them here. The lack of information about the fermentative characters of *Mycobacterium tuberculosis* has been due to the difficulty experienced in finding a simple yet satisfactory basic sugar-free liquid medium that will support the growth of the bacillus. One of us (J.B.), after numerous trials, has evolved a medium which appears to satisfy the necessary requirements. This medium is prepared as follows. The white of one egg is thoroughly mixed with 200 ccm of tap-water. The mixture is then boiled for five minutes, filtered through a thin layer of cotton-wool, and cooled. One per cent of sugar and 3 per cent of litmus, or 1 per cent of Andrade's indicator, are added, and the medium is put into small screw-capped bottles containing gas tubes and sterilized. In this medium most of the strains of *Mycobacterium tuberculosis* that we have tested have grown slowly but quite vigorously at 37° C. The fermentative reactions have begun after some three weeks incubation. We have kept our cultures for an arbitrary standard period of six months, comparing them with uninoculated controls, none of which has shown any appreciable change in reaction over that period. Up to the present we have tested thirty strains of *Mycobacterium tuberculosis* isolated from various human sources, upon the four sugars, dextrose, lactose, mannite, and saccharose. Four of these strains failed to grow in any of the sugar media. Of the remaining twenty-six all have produced acid without gas in lactose, twenty-five have produced acid without gas in dextrose, twenty-one have given the same reaction with saccharose, and three have attacked mannite.

We wish it to be clearly understood that our investigations are only in a preliminary stage. We have not had an opportunity of checking them properly and we are therefore not certain that they are accurate. We hope, however, that some other worker with more time for research may be sufficiently interested to pursue this investigation further.

The May number contains a brief account of the German Congress of Surgery in Berlin from March 31 to April 3, a programme of the coming Reunion Médico-Chirurgicale de Morphologie in Paris on May 19, a summary of the contents of the fourth (December 1936) bulletin of the last named society, and an announcement of the arrangements being made to promote associations between the universities of France and Germany.

ADVANCED EXTRA-UTERINE PREGNANCY

BY

A. PATRICK, M.B., F.R.C.S. Ed.

Honorary Assistant Surgeon Hull Royal Infirmary

(WITH SPECIAL PLATE)

Extra uterine pregnancy is not a very common condition, although within the last two decades it appears to have become more frequent, this probably being due to greater accuracy in diagnosis. Advanced extra uterine pregnancy is, however, still a rarity, and the following case is worthy of mention from that point of view alone.

Case Record

Mrs. A., aged 33 years, was admitted to hospital on September 12, 1935, suffering from severe abdominal pain, sickness and vomiting, and collapse. The previous history showed that she was well advanced in pregnancy. Her last menstrual period commenced on April 16, 1935. During the first few months of pregnancy she complained of severe sickness and vomiting which was always accentuated at the suppressed menstrual periods. After the third month the nausea and vomiting became much less. During the second and third months of pregnancy she had several what she termed bad attacks of lower abdominal pain, associated with an increase in the sickness and vomiting. The abdomen just above the pelvis was always very tender to the touch. At no time during the pregnancy was there any uterine haemorrhage.

Past History—The patient had been married for six years, during which time she was never pregnant. She had consulted her family doctor about her sterility, and in fact, it had been suggested that she should have a dilatation and curettage. Her menstrual history was that the menses were always regular—every twenty-eight days and lasting six to seven days. There was no history of leucorrhoeal discharge or of any frequency of micturition. She had always enjoyed perfect health, and there have been no previous serious illnesses.

Examination—The patient looked extremely ill. She was absolutely blanched and her respirations were of a sighing character. Every time she attempted to sit up in bed she collapsed. Her pulse rate was 120, rapid and feeble. Her tongue was dry and she complained of great thirst. Her conjunctivae were practically colourless. She had severe abdominal pain associated with sickness and vomiting. The abdomen did not move on respirations. There was a fullness of the lower abdomen in the middle line. The abdomen was held very rigid and she complained of the greatest tenderness in the left iliac fossa. On vaginal examination, which was extremely difficult owing to the rigidity of the abdominal muscles, one could palpate a large mass filling the pelvis. This I considered was the normal pregnant uterus. Other signs of pregnancy were well advanced.

Diagnosis—It was obvious from an examination of the patient that the condition was a very acute one and that she was suffering from internal haemorrhage, which I considered was due to a ruptured uterus. The fact that she had had no uterine haemorrhage during the pregnancy and that the pregnancy was so advanced made me disregard the probability of this being a ruptured ectopic gestation. However, the seriousness of the condition was realized and I advised immediate operation.

Operation—On September 12, under general anaesthesia, the abdomen was opened through a lower mid line incision. On reaching the peritoneum I noted the bluish black coloration behind it indicative of intraperitoneal haemorrhage. On opening the peritoneum I found the abdominal cavity filled with partly clotted and partly fluid blood. In the lower part of the wound was a large mass and through a tear in the free surface of this mass could be seen a foetus covered by the amniotic sac. On further examination it was found that this was a large ectopic gestation. The uterus was slightly enlarged and congested. Both ovaries were normal. I resected the

grossly distended Fallopian tube, and then hastily removing all the large pieces of blood clot, closed the abdomen. No intravenous saline was given and the patient rapidly improved, within two weeks she had made a complete recovery.

Specimen

The large mass to the left as shown in the photograph is the grossly distended Fallopian tube. The placenta with the vessels running over its surface can be plainly seen, firmly attached to the Fallopian tube. The amniotic sac was opened and the foetus placed in this position in order to photograph it (see Special Plate).

Commentary

According to Schumann ectopic gestation occurs in only 1 in 267 pregnancies, or 0.38 per cent. The age incidence, according to Wynne, is between 24 and 33 years.

The position of the gestation varies. It can therefore be (1) cornual, (2) isthmal, (3) ampullary, (4) tubo ovarian or (5) ovarian. The commonest type is the ampullary, into which category this case belongs. This part of the tube is capable of great distension, and allows an ectopic gestation to develop much further than any other part.

Numerous conditions, such as inflammation in the lower pelvis, salpingitis, diverticulitis, and appendicitis, have been found to be predisposing factors to ectopic gestation, but in this case no history could be obtained of any such cause, nor was there evidence of anything pathological in the other tube. Congenital anomalies are often cited, and this might well have been the case here, but I have no proof.

It is common in cases of ectopic gestation to find that there is some history of sterility. Farrar quotes 16.6 per cent of cases in which ectopic gestation followed a long period of sterility, and 30 per cent in which there had been one previous child.

One interesting feature in the present case was the absence of the atypical menstruation as described by Bandler. In the majority of cases some slight uterine haemorrhage is complained of, but here the patient strongly denied that there had ever been any.

Schumann states that the greater proportion of ectopic pregnancies rupture at the eighth week, and that very few continue after the twelfth week of pregnancy. The most interesting point about the case here recorded was the fact that the pregnancy developed up to nearly five months.

I wish to express my indebtedness to Dr D. Stenhouse Stewart, who took the photograph.

L. T. Davidson, K. K. Merritt, and T. T. Chapman (*Amer. J. Dis. Child.* January, 1937, Part I, p. 1) gave eighteen premature and fifteen full term infants irradiated evaporated milk during the first six months of life to determine the degree of protection from rickets afforded by this means alone. Judged by x-rays none of the eighteen premature infants were entirely free from rickets, six showed slight, nine moderate and three marked rickets. Of the fifteen full term infants four were free from x-ray signs of rickets throughout the period of the study, one had moderate rickets and in the other eleven there was only slight rickets. In the group of premature infants in this study who were given irradiated evaporated milk as their sole source of vitamin D the rickets tended to develop earlier than in the full term infants. Irradiated evaporated milk has been shown to be considerably less efficacious for the protection of the premature infant against rickets than is metabolized vitamin D milk. When the two are given under identical conditions the inferiority of the irradiated milk is believed to be due entirely to the smaller concentration of vitamin D units.

PRONTOSIL BY THE INTRAPLEURAL ROUTE

TWO CASES OF STREPTOCOCCAL EMPYEMA

BY

JAMES L. BROWN, M.B., M.R.C.S.

Resident Medical Officer Birkenhead Municipal Hospital

(WITH SPECIAL PLATE)

Now that the spate of writing for and against prontosil has lined down to a clearer stream it may be opportune to report two cases in which the dye was used with considerable success in the pleural cavity.

These two cases are interesting in that they both occurred after influenza, both patients were in extremely poor general condition (in one case there were several complicating factors) and in both the favourable progress could be attributed directly and almost entirely to prontosil.

Case I

A married woman aged 39 was admitted to the Birkenhead Municipal Hospital on January 28 1937 with a five-days history of influenza. She had several rigors at the onset of her illness and these were followed by joint pains backache, headache anorexia and nausea. On the day before admission a severe pain had commenced in her left chest and she was beginning to be short of breath. She was two months pregnant. Her previous ailments included erysipelas two years earlier for which she had had anti-streptococcal serum intravenously.

On examination the patient was in poor condition pale, cyanosed and dyspnoeic. Her temperature was 102.8° the pulse rate 126 and the respiratory rate 38. Her physical signs were those of left basal pleurisy with commencing consolidation of the middle and lower zones of the left lower lobe. Her urine contained a trace of albumin but no pus organisms or casts. During the next five days the temperature fell by 1.5° but her general condition remained poor. She was listless and strange in manner and at times appeared to be in a low delirium. The albumin in her urine increased and a specimen taken a week after admission showed many leucocytes some red blood cells squamous epithelial cells and coliform bacilli. By this time she was tender in the left renal angle and a diagnosis of pyelitis complicating an influenzal pneumonia was made.

On February 6 she passed an abortion of about ten weeks development with very little post partum loss. Contrary to expectation no symptoms of retained products or pelvic infection followed and the abortion had very little effect on her general condition. For the pyelitis a course of mandelic acid was instituted and her urine cleared completely within the next two weeks.

four days later 3 oz. of very thin red turbid fluid were removed. This again was sterile. The procedure was repeated at intervals with the complete disappearance of pus and re-expansion of the lung. On April 1 her chest was pronounced clear, and a radiograph taken on that date demonstrated complete absence of fluid (Fig. 2). All her symptoms had disappeared, she was several pounds heavier than on admission and her urine and sputum were satisfactory. As this radiograph had shown a 'pleural ring' a bronchography was undertaken by me, and the ring shown to be an emphysematous bulla in a normal bronchial tree with no evidence of the bronchiectasis which so often follows influenzal pneumonia. The patient was discharged in excellent condition on April 10, 1937.

Case II

A married woman aged 37, was admitted to Birkenhead Municipal Hospital on February 12 1937. She gave a history of the onset of pneumonia five days previously, following an attack of influenza.

On admission her temperature was 101°, the pulse rate 100 and the respiratory rate 32. She was pale dyspnoeic, and slightly cyanosed. Her physical signs were those of complete consolidation of the left lower lobe with a small pleural effusion. On aspiration this was clear and slightly straw-coloured. The size of the effusion increased, and on February 16 a further aspiration showed the effusion to consist of a thick creamy pus. Culture from this pus showed streptococci only and after aspiration of 12 oz. all distress disappeared. A radiograph after this aspiration showed a small amount of fluid surmounted by a zone of consolidation which was thought to be tuberculous. Repeated examinations of the sputum for tubercle bacilli were negative and the empyema gradually increased the organism found at each aspiration being the streptococcus.

On March 8 12 oz. of thick pus were aspirated, and as all the sputa had been negative for tubercle bacilli it was decided that rib resection in the near future was indicated. As in the previous case 5 ccm. of prontosil soluble were injected into the pleural cavity in an effort to minimize the risk of infection at operation. Three days later the pus was found to be thinner and red in colour and on culture showed no growth of organisms. The pus was seen in subsequent aspirations to become progressively thinner and finally no fluid could be obtained on aspiration. Specimens from each aspiration were sent to the laboratory but no organisms were found after the injection of prontosil. The consolidation gradually resolved and the patient was discharged on April 14 with no clinical or radiological traces of her illness other than a slight thickening of the pleura at the left base.

Conclusions

1 Both these patients who were extremely ill were saved from any operative procedures.

2 In both cases the recovery was complete.

3 In both the organism was the streptococcus and the improvement immediately followed the injection of prontosil.

4 It is reasonable to assume that this hitherto unpublished route of administration of prontosil has a place in the treatment of streptococcal empyema.

I am indebted to Dr. R. A. Grant medical superintendent of Birkenhead Municipal Hospital for permission to report these cases.

D. Gilbert (*Brit. med. J.* March 21 1937 p. 779) reports nine recent cases of benzol poisoning in female workers employed in Belgian mirror factories to varnish mirrors which have been silvered. The second protective coat of varnish applied after silvering is a solution of gum resins in benzol. Three deaths have occurred so far. The clinical picture is one of varying multifocal small and large haemorrhages and severe apastatic anaemia.

Clinical Memoranda

Partial Extra-uterine Pregnancy

(WITH SPECIAL PLATE)

On September 4, 1935, I saw a female patient, aged 27. She was pregnant and roughly at full term, and had spasmodic pains referred to the right iliac fossa which had lasted six days, becoming more severe during the last two days. There had been no "show". On examination it appeared that the presentation was a transverse one with the buttocks in the right iliac fossa. The os was not dilated. Caesarean section had been performed in February, 1932, but she was not aware of the reason. As the patient was somewhat exhausted with the pains, and in view of the fact that the presentation was a transverse one, and that the os was still closed, I decided to send her into hospital for Caesarean section.

OPERATION

At operation a very interesting state of affairs was revealed. A mid line incision was made, and on incising the peritoneum I was surprised to come down straight on to the child's buttocks and lower limbs. The child was delivered with very little difficulty and then one could see what had happened. The old scar in the uterus had "gaped" and the sides of the gap had become adherent to the parietal peritoneum. The child's buttocks and legs were outside and the head and upper part of the body were inside the uterus. The placenta was mostly in the uterus, but part of it extended over the right edge of the gap. As the gap was so wide and the edges "rounded off" a hysterectomy seemed the most reasonable thing to do. This was done and both mother and child made an uneventful recovery.

There was a fairly deep open sore running across the outside of the child's left thigh in the region of the trochanter, and this was apparently due to pressure on the edge of the gap in the uterus. At the end of three weeks this healed satisfactorily and really left very little deformity. The only other feature was that the child had slightly clubbed feet, but these also fully recovered at the end of three weeks daily manipulation.

COMMENT

The photograph (see Special Plate) shows the gap in the uterus and the "rounded edges". It would seem that the child must have grown through and stretched the old scar in the uterus during the period of gestation. It appears that this must have been a gradual process, as so far as I have been able to elicit from the patient the pregnancy followed a normal course with no unusual symptoms suggesting a sudden rupture.

Barrow-in-Furness

A Case of Vesico-colic Fistula

A case with certain striking features came under my observation for the first time some years ago and I have had an opportunity of seeing the patient from time to time since.

CASE REPORT

A man aged 58 came to see me in the first instance complaining of swelling of the right testicle. I found him to be suffering from epididymo-orchitis on the right side but was unable subsequently to discover any connexion between this inflammatory condition and the events which followed. The urine contained pus and many threads, and rectal examination

revealed no prostatic enlargement, though there was some thickening of the bladder base above. I prescribed the necessary treatment for his testicular condition and did not see him again for four months. On the occasion of this second visit he complained of the faecal odour of his urine which he said he had noticed on and off for several weeks. A specimen of his water was chocolate-coloured and had a strong faecal smell.

Cystoscopy showed a recess at the junction of the left lateral and posterior walls of the bladder and intravenous urography revealed slight dilatation of the left ureter, otherwise the urinary tract appeared normal. A barium enema made it quite clear that diverticulitis was present in connexion with the pelvic colon. In the circumstances I recommended that the patient should have a colostomy. This was not carried out until five months later, when another surgeon performed the operation. Immediate relief from the urinary symptoms resulted from this intervention: evidence of faeces in the urine slowly disappeared but about six weeks after the operation spasms of pain were felt in the bladder. As time went on these were increased and urgency and frequency slowly became more and more prominent.

I did not see the patient again, however, until nine months following his colostomy when his condition was truly pathetic for he screamed with pain every time he micturated. He had been suffering such agony on passing water that his doctor had found it necessary to give him morphine daily over a period of some months. At the time I saw him actually he had been having 8 grains daily.

Cystoscopy showed vesical calculi to be present in the bladder. Litholapaxy was contemplated but I found that in trying to distend the bladder the fluid simply ran out through the colostomy opening. I was therefore forced to carry out suprapubic lithotomy in spite of the presence of his sub-umbilical colostomy. Three stones were removed: the largest the size of a plum, the other two just a little smaller. After removal of the stones the patient did well and there was no difficulty in getting him quickly off the morphine, as the cause of his distress had now gone.

The connexion between the bladder and the bowel must have closed eventually because six months after my operation I was called out to see this patient again with acute retention of urine. The colostomy was still functioning well and there was no question of urine escaping at this time through the opening. I relieved his retention by catheterization, and took the opportunity of dilating the bladder neck with a large sound. This apparently had a beneficial effect for he subsequently passed water freely. At this stage there was no sign of any faecal content in the urine.

COMMENTARY

One fact which is perhaps of academic rather than practical interest is that although faecal material had been entering this patient's bladder for many weeks without interruption at no time was there the slightest evidence of pyelonephritis. Such an experience seems to give a very definite answer in the negative to the question: "Does infection ascend to the kidney from the bladder by way of the lumen to the ureter?"

If such a route is a common one surely the circumstances in this case were ideal for infection to occur in this way. Actually I would go so far as to say that I was particularly struck with the appearance of good health of the patient during the time that his vesico-colic fistula was allowing a free communication between the bowel and the bladder.

It is now two and a half years since I last saw this patient and I have just heard from him—four years after the colostomy—that he is in excellent health, he has had no further difficulty in passing his water, there has been no recurrence of faecal contamination of the urine and the colostomy is working well.

H. P. WINSBURY WHITE, F.R.C.S.,
Surgeon, St. Paul's Hospital.

London

Injection Treatment of Hernia

The injection treatment of hernia has definitely established its value. The following clinical history is illuminating.

A man aged 65 years consulted me on July 28, 1936. Twenty-two years previously he had developed an inguinal hernia. In 1933 he underwent an operation for strangulation. A few months later the hernia recurred. Again, in 1934 a herniorrhaphy was performed. In a short time the hernia once more reappeared. Both operations were done by competent surgeons. Examination revealed a right inguino-scrotal hernia. The injection treatment was commenced on July 31, 1936. The sclerosing fluid obliteration was used. It is prepared according to Mayer's formula. The injections were given at weekly intervals. Except for the first which was 0.5 ccm., the amount of obliteration injected at each treatment was 1 ccm. The necessary surgical technique for the successful performance of this procedure was very carefully observed. One may briefly mention that the needle was inserted vertically over the site of the internal ring until the point was felt to pierce the aponeurosis.

The final injection was given on December 2, 1936. On January 27, 1937 the hernia being now cured, the patient discarded his truss.

Interesting features in this case are (a) the patient had been twice previously operated on for hernia, (b) his age in no way interfered with the success of the treatment.

Reviews

HUMANISM AND MEDICINE

Humanisme et Médecine. By Joseph Olinczyc. (Pp. 140, 12 fr.) Paris: Labergerie, 1937.

The *Oxford English Dictionary* gives four quite distinct meanings for the word 'humanism'. The sense in which Dr Joseph Olinczyc uses it in his book *Humanisme et Médecine* is the least technical of these—that defined in the dictionary as "the character or quality of being human, devotion to human interests"—and yet even this does not indicate quite the connotation which the author attaches to it unless it be remembered constantly and prominently that the 'soul' is as essentially part of the 'human' as is the body or mere intelligence. He emphatically does not mean a system of thought or action which is concerned with merely human interests (as distinguished from divine) or with those of the human race in general (as distinguished from individual) or devotion to literary culture, though he has a section in which he insists on the value of the study of 'the humanities' in the latter sense for the practitioner of medicine.

It is a short book but excellent of its kind. In scope it covers, though not so fully except as regards one matter, much the same ground as the central chapters of Sir Henry Brackenbury's *Patient and Doctor* dealing with the essentials of the relations, ideal and actual, between those two persons as individuals with the reasons for maintaining these essentials at all costs and with the way in which communal or social medicine should be developed strictly within its own sphere so that it shall not violate them. In his treatment of the subject and in his style the author admirably displays those French characteristics which we have learned to value so highly—a strict and consistent logic, a remarkable succinctness of expression and a power of indicating with few words important shades of thought and meaning.

Il ne faut pas ramener la charité personnelle et fraternelle au sentiment de solidarité sociale et collective, toutes deux sont nécessaires et ne sauraient s'exclure. Mais elles salimentent à des sources différentes, l'une aux aspirations éternelles de la personne, l'autre aux droits incontestables et légitimes de l'individu. Cultivons l'une et l'autre, mais ne laissons pas, au seul profit de la solidarité sociale, effacer la charité de la surface de la terre.

The whole short book is an example of wise thought and skilful presentation

PRACTICAL ANATOMY

A Manual of Practical Anatomy A Guide to the Dissection of the Human Body. Part III The Head and Neck. By Thomas Walmsley. New edition (Pp 357, 133 figures 12s 6d net.) London Longmans Green and Co 1936

The new edition of Part III of Professor T Walmsley's manual gives a clear, concise account of the essential facts of human anatomy, and is written with the primary object of providing a guide to dissection, but it is also intended to be an introduction to the further study of anatomy in the larger systematic textbooks and to give some indication of the bearing of anatomical facts on general practice. The present volume deals with the head and neck, and the description is chiefly confined to matter which can be verified in an ordinary dissection, while details of microscopical structure and the development of special organs are not included. The book is well written, and bears the hall mark of the practical observations of an experienced teacher.

The illustrations are in general good, and the three x ray plates of the skull, with explanatory diagrams may be specially mentioned. Some of the schematic diagrams, however, might be improved by the inclusion of some localizing landmarks—for example, a thin outline of the eyeball and optic nerve in Fig 68—and a more accurate representation of the proportional size and relations of the various parts should be attained. In the diagram alluded to the ciliary ganglion is shown with diameters greater than the transverse diameter of the internal carotid artery. Other diagrams—namely Figs 108 and 117—are capable of a more faithful representation of the structures depicted, with a proportional gain in clearness and accuracy. In our opinion a careful drawing from the original of the principal parts in their correct relations and proportions with a few simple orienting lines, is much more readily comprehended than schematic drawings without such a guide, the latter being comparable to a map of London without any indication of the River Thames. The compilation of the book as a whole has, however been very carefully conceived and carried out and judging from the popularity of the preceding volumes it should prove a valuable guide to students in the dissecting room. It supplies a fund of information presented in an interesting and attractive manner.

DERMATOLOGY AND SYPHILOLOGY

The 1936 Year Book of Dermatology and Syphilology. Edited by Fred Wise M.D. and Marion B. Sulzberger M.D. (Pp 720 illustrated 3 dollars or 12s 6d.) Chicago Year Book Publishers London H K Lewis and Co 1937

We welcome once more the yearbook produced by Dr Wise and Dr Sulzberger whose annual study of current literature always yields matter of considerable interest to their professional brethren. This year they give a special chapter on urticaria in which they summarize current views and theories on this important and baffling subject.

Notwithstanding the vast amount of work done on chronic urticaria during recent years, very little real progress has been made in its management and the riddle of its aetiology remains unsolved. Only in those comparatively rare cases in which it can be traced to a single allergen, such as feathers, pollens, etc., has the problem been solved. In the far commoner type of case where there is general sensitiveness we still remain in the dark and the vast number of drugs recommended for urticaria demonstrates conclusively how unsatisfactory the treatment is. Other subjects accorded prominence in the *Year Book* are the therapeutic control of syphilis and other venereal diseases and drug eruptions, including the toxic results of 'slim' (the name under which dinitrophenol is sold to the public for the treatment of obesity), a drug which may cause polyneuritis, bilateral cataract, severe pruritus, or even death itself. The highly important subject of industrial dermatitis, including its prevention, is also touched upon. The general practitioner will welcome the large amount of space devoted to therapy in this volume, and he may glean some guidance for the task of utilizing those fashionable remedies, the endocrines, with more intelligence and less optimism than the chemical manufacturers expect him to display. The authors are not blind to the dramatic side of disease, and we may say in conclusion that they have produced both a useful and an interesting volume which deserves attention from all who are concerned in these specialities.

BROMPTON HOSPITAL REPORTS FOR 1936

Brompton Hospital Reports Vol 5 1936 (3s post free). Copies from the Secretary, Hospital for Consumption, Brompton SW3

The slim attractively bound volume issued every year by the Brompton Hospital is now familiar to many of our readers, and the latest of the series will be welcomed. Like its predecessors it contains papers recently published elsewhere by the staff of the Brompton Hospital and the Frimley Sanatorium, in addition there are three special statistical reports, based on figures derived from experience gained in the hospital. The latest volume is almost entirely concerned with various aspects of pulmonary tuberculosis: infectivity, latency and immunity, relapse after cure, and thoracoplasty being some of the aspects of the disease discussed. A notable contribution is the survey of the surgery of pleural and pulmonary infections made by Mr J E H Roberts in the Littenstone Lectures delivered before the Medical Society of London in 1935. To the two papers by Dr R C Wingfield we should like to draw particular attention. The clinical study of relapse in pulmonary tuberculosis "will prove of much assistance to all workers concerned with the diagnosis and treatment of this disease. Sub Jove Frigido is a thoughtful and vigorous attack upon the concept 'sanatorium treatment'—a concept which in the light of the most recent knowledge of the treatment of pulmonary tuberculosis should now become obsolete. This paper deserves wide publicity among not only tuberculosis workers but also local authorities who might be made to realize how ineffectively public money is being spent at present in some directions and how unwisely withheld in others.

Yet another paper by Dr Wingfield (with Dr Margaret Macpherson) gives the results of a mass investigation of healthy adolescents. This investigation deserves the fullest sympathy and encouragement as it forms the first piece of research of this kind relative to tuberculosis in this country. Unfortunately its scope, restricted to 1,000

logical examination limits the conclusions that such an investigation might yield. The three statistical reports deal with the Brompton experience of thoracoplasty, pulmonary abscess and the radon treatment of pulmonary neoplasm. Since 1932 thoracoplasties have been performed in increasing numbers every year and now total 437. At present the operation is being done in 6 per cent of all patients with chronic pulmonary tuberculosis admitted to the wards of Brompton. The operative mortality is about 14 per cent., and the expectation of survival in those B3 patients who are suitable for thoracoplasty is three times as great as that of the average B3 patient. Of the survivors about 15 per cent are clinically cured. In the third report it is stated that there is no evidence that radon in any way prolongs the lives of patients suffering from carcinoma of the bronchus.

We should like to make a final reflection. Reviewing the *Brompton Hospital Reports* for the last five years one is forcibly struck by the absence of research on morbid anatomical, biochemical and bacteriological lines, or on their correlation with the clinical aspects of tuberculosis. In view of the unique opportunities of the hospital and its sanatorium this is to be deplored.

Notes on Books

The text of Dr DONALD HUNTER'S four valuable lectures on Occupational Diseases given to the Derby Medical Society in May 1935 which were published as clinical supplements to the *Guy's Hospital Gazette* have now been reprinted in book form with an index and copies are obtainable (price 9s.) from H. K. Lewis and Co. Ltd., 136, Gower Street, London, W.C.1.

The nineteenth edition of Stilling's *Pseudo isochromatic Plates for Testing Colour Perception* appears in its English garb under the editorship of Professor James Drever of Edinburgh and is published in that city by F. Bauermeister at 22s. 6d. The present edition which comes sixty years after the first, shows little departure from the last one. As in the Ishihara test and the Edridge-Green test, in common use in this country, the principle underlying Stilling's charts is the reading of numbers and the picking out of like-coloured dots against a background of confusion colours. On the Continent Stilling's chart seems to have the wider circulation. It has a larger range of tests for yellow-blue sensitivity.

Materia Medica, Toxicology and Pharmacognosy by Professor W. MAXIMOW (H. K. Linton, 30s.) is a textbook

Preparations and Appliances

A MODIFIED BRONCHOSCOPE

Dr J E G MCGIBBON (Liverpool) writes)

The modifications of the ordinary bronchoscope about to be described are mostly those of other writers, but they have been assembled and combined into one instrument with the generous advice and help of Mr Percy G Phelps of Messrs. Mayer and Phelps Ltd. Fig 1 shows the modified bronchoscope which can be made in various lengths and calibres—it has been found that for inspection of the main bronchi a bronchoscope of 39.5 cm. with an inside diameter of 10 mm. is most useful for the secondary bronchi an instrument 44.5 cm by 8 mm permits of an easy and well illuminated view while a tube 48 cm by 7 mm is used for the more distal bronchi. The tube is similar to the Jackson model save that the proximal inch is widened in the vertical axis so that the inlet of the tube is oval in order to facilitate the introduction of endoscopic instruments. Originally the instrument was equipped solely with the dual projected lighting system as used in the Negus laryngoscopes and oesophagoscopes, and we are indebted to the patentee—Mr R. Schranz of the Genito-Urinary Manufacturing Company Ltd—for permission to incorporate this system of lighting in the instrument. Later

plug into the sockets B. These sockets are lateral to those for the dual lighting system at the proximal end of the bronchoscope. By means of the hinges the telemagnifier can be tilted instantly out of the field so that instrumentation through the tube can be carried out with the telemagnifier either in position or tilted up as desired.

Fig 4 shows a special upper lobe bronchoscope which is lighted as described above and which can be used with the telemagnifier. It is designed after the model of F Vistreich of New York (*Arch Otolaryng.*, 1935 22 634). The dimensions of the bronchoscope are 36 cm by 10 mm and its distal end is cut to form a double V. At the apices of the Vs is hinged

FIG 1

FIG 2

FIG 3

FIG 4

it was suggested by Mr R. Doyle, resident surgical officer, Royal Southern Hospital, Liverpool, that the value of the bronchoscope would be enhanced if distal lighting were added as not only would this increase the illumination for direct inspection of the bronchus but it would permit also of the use of the Pinchin Morlock telescopes (*Lancet* 1932 1 671) through the instrument. Fig 2 depicts the special holder for use with these telescopes. The dual lighting system is removed and the telescope holder is then fitted into the sockets usually occupied by this system. Fig 3 illustrates a "telemagnifier" as devised by S. Israel of U.S.A. (*Ann. Otol. Rhinol. Laryng.*, 1935 44, 285). The telemagnifier gives a magnification of 34 diameters; it is light in weight, causes no respiratory obstruction, and can be focused to different distances for use with tubes of various lengths. It is mounted on two rods which are hinged at A near the points where they

a small stainless steel mirror which is sufficiently large to reflect the entire image of the orifice and proximal portion of the upper lobe bronchus. The angle of the mirror is controlled by a screw mechanism at the proximal end of the instrument which can be operated easily by the thumb. It is necessary to point out that the interpretation of the mirror image thus obtained requires some practice but that once this technique is acquired the information procured is of great interest and value.

The instruments briefly described above give very excellent illumination; they possess a good working lumen and they can be used either with distal or proximal magnification. They have been in use regularly for two years in a bronchoscopy clinic and have given satisfaction. They are made by Messrs. Mayer and Phelps Ltd., of New Cavendish Street, London W 1.

SATURDAY JUNE 5 1937

TREATMENT OF HERNIA

The growth of operative surgery has been so rapid and so striking that some of the changes that have taken place may not be readily appreciated. The comparative safety of operations to-day has led to a great diminution, if not disappearance, of those advanced conditions which were seen at one time because operation had been avoided on account of the high risk then associated with it. Goitres reaching down to the umbilicus and scrotal herniae as low as the knees, so that the sufferer constantly wore an overcoat to hide his deformity, are no longer seen, yet these were by no means rarities in the early days of Listerian surgery. There have been changes not only in the type of condition calling for surgery but also in the methods of treating certain conditions: this is particularly true of hernia. Since the war there has been a wider use of fascial sutures for the larger hernias, especially those of the inguinal variety; surgeons have been increasingly influenced by physiological principles, and such mechanical devices as filigrees have been almost universally abandoned. In the treatment of oblique inguinal hernia in healthy young adults due respect is now being paid to the sphincter action of the conjoined tendon, and efforts are being made to preserve the inguinal sphincter and not destroy or distort it by cutting or suturing. It is everywhere realized that in young healthy patients with oblique inguinal hernia the complete removal of the sac is what is really needed. The Bassini operation and allied procedures which comprise stitching the conjoined tendon to Poupart's ligament in many cases unnecessarily interfere with the natural beauty of a delicate sphincter mechanism. This was emphasized during a debate on the treatment of inguinal hernia at a meeting of the Surgical Section of the Royal Society of Medicine in December of last year. Efforts have also been made of late to revive the treatment of hernia by injections into the sac. This revival has coincided with the recent popularity of the injection treatment of varicose veins, haemorrhoids, hydroceles, and other conditions which were once treated in this way but which with the development of Listerian surgery had become the almost exclusive province of

operative surgery. The pendulum has swung in the opposite direction. If to-day we no longer degrade port by injecting it into hydrocele sacs, but use more appropriate sclerosing solutions, the principle is unaltered: to some extent there has been a reversion to pre-Listerian practice. The presence of a preformed sac in cases of oblique inguinal hernia is now universally accepted as one of the chief aetiological factors, and is probably regarded by most surgeons as the all-important one. In such cases the processus vaginalis remains open in part or throughout, and the physiological process of peritoneal oblitative fusion which normally takes place has been defective or absent. It is reasonable to suppose that by injecting suitable sclerosing solutions into the sac this oblitative process may be induced artificially, and, provided there is elimination of the sac, there should be cure of the hernia.

The injection treatment of hernia, like that of hydrocele, is no new thing. In the year 1832 George Heaton of Boston¹ used *Quercus alba* for injection into hernias, and in 1835 Valpeau in Paris found that a patient whose hydrocele he had injected with an iodine solution had been cured of his hernia also. Valpeau subsequently treated three cases of hernia by incising the inguinal canal and the sac and flushing the wound with iodine solution. Others used essential oils, cantharides, alcohol, and other substances, but the increased safety and popularity of operative surgery and the successful results of the radical cure of hernia did much to overshadow the injection treatment. It was for the most part given up, but within recent times interest in it has been revived once more. That this interest has come about rather belatedly is not surprising when we consider the scepticism with which the injection treatment of varicose veins was at first received by the profession. In this country particularly there has, with few exceptions, been but little interest in the procedure. Delisle Gray has perhaps done most to bring it to the notice of the profession, and early this year the matter was debated in the correspondence columns of the *Journal*. In Spain and in America, on the other hand, the injection treatment of hernia has attracted considerable attention. By 1931 Mestre² of Barcelona had treated 10,000 cases of hernia by injection without mortality. Numerous articles on this method have recently appeared in the U.S.A. the *Annals of Surgery* for March 1937, for example contains five papers by workers in the department of surgery in the University of Minnesota and another paper appears in the

THE TAVISTOCK CLINIC

THE BRITISH
MEDICAL JOURNAL

March issue of the *Canadian Medical Association Journal*. The selection of appropriate cases is of the greatest importance only reducible hernias capable of proper control by a truss are suitable, and the small reducible inguinal hernia appears to be the most suitable. The solutions employed have been many and varied, and include such constituents as phenol, alcohol, tincture of thuja glycerin, and Canadian pine extract, the technique is a specialized one. Any number from four to twenty or thirty injections may be necessary, and the object appears to be to produce a fibroblastic reaction of a plastic character, which not only seals off the sac but also closes the inguinal canal. It is claimed that with care complications are singularly few, and there can be no doubt that in those who have a horror of operation, or in cases in which other special circumstances arise, the cure of hernia by an ambulant method which ultimately allows the patient to discard his truss has something to be said for it.

THE TAVISTOCK CLINIC

Everyone knows by now the work of the Institute of Medical Psychology. The Tavistock Clinic was founded in 1920 at a house in Tavistock Square London, to treat patients suffering from the neurotic disorders which are a serious and a growing handicap to the community in these days of rapid change and great stress. The need for the clinic was proved by the long waiting-list which quickly accumulated. As its work became known and its revenue increased, its council took a lease of the abandoned packing department of Shoobred's in Malet Place, and reconstructed this as a modern and efficient out-patient clinic with a children's department. The charity then took the name of the Institute of Medical Psychology, for it is not only a treatment clinic, but a centre of research and teaching in practical psychology. Many specialists and general practitioners of medicine have fitted themselves at the clinic to deal expertly with neurotic illness. Certain commercial concerns have however imitated the new name and real confusion has resulted possibly to their advantage but not to that of the clinic. The council has therefore decided to readopt the old name of "The Tavistock Clinic," with "The Institute of Medical Psychology" as a subtitle and a letter announcing this by Sir Henry Braeklenbury, appeared in our issue of April 17. Old friends of the institution will probably be pleased that the associations of the pioneer days are to be perpetuated.

All however, is not well, for the clinic is in very serious need of money. It maintains an in-patient hostel in Endsleigh Street but the lease expired a few months ago and the council had not nearly enough funds to build and equip a hostel on a new site which it had acquired. Fortunately the threat of a complete loss of in-patient accommodation has been averted for a time, as the lease of the present in-patient department has been extended until midsummer, 1938. The council, however, is in urgent need of the financial help which will enable it to proceed with its plans for a new hostel, which must be in working order by that date. It may also have to spend money immediately on improving the fire precautions in the present hostel. Nor does the shortage of money affect the clinic's in-patient work only. Unless it can obtain much better support, the council says in its report for 1936, it will have to curtail the present work drastically besides abandoning its most promising and partly accomplished extension—the care of in-patients. We cannot do better, in stating the need of the clinic than use the council's own language. "Here is a hospital which was the pioneer in a field now recognized as of the first importance in regard to the national health which is doing work of a very high standard indeed and showing constant results which are gratifyingly successful which has waiting at its doors for attention large numbers of patients urgently requiring help and ever clamouring for succour, which has all its plans ready for that enlargement which is essential for meeting the increased demand daily made upon it, but which is crippled in its beneficent activities and even brought into jeopardy by a general lack of appreciation of its purpose and its needs not surprising at an early period but amazing to-day."

In addition to its ordinary appeal and indeed to the special appeal which it is now addressing to the general public the council is making a special effort to attract the help of the industrial community and especially that of large employers of labour. Official figures show that not less than one-third of the total incapacity of employed persons in this country can be attributed to neurotic illness. Quite apart from this appalling figure, there is an immense amount of unrecorded and even unrecognized inefficiency due to minor degrees of neurosis. If the public realized the loss of damage and misery caused by neurotic illness in its great variety of forms appreciated the possibility that the Tavistock Clinic—in conjunction with a sufficient number of affiliated treatment centres—could greatly reduce the incidence of neurosis and gave it the support it deserved th

improvement in the health and the happiness of the community, not only in mind but also in body, would be tremendous. Everyone who possesses insight into the mental needs of the community will support the Tavistock Clinic of Malet Place as energetically and generously as he can.

field. It is hardly likely that any animal will be found to rival the rat in its capacity for transmitting a variety of diseases, nor will many afford discoveries of such general interest as the infective tumours of wild rabbits recently brought to light in America but these examples will serve to show what may lie hidden in a territory which seems to have been neglected.

TUBERCULOSIS IN VOLES

Widespread interest has been taken in a report by A. Q. Wells¹ on the first results of his investigation of disease in wild voles. It was observed some years ago that these animals appeared to be subject to periodic fluctuation in numbers the population increasing for several years and then diminishing greatly in a few months. The nature of the conditions causing this was quite unknown and the object of Wells's work was rather to study factors controlling the spread of epidemic disease than merely to establish its nature in this particular case. The immediate results are quite unexpected for they are that voles trapped in uncultivated areas in England, Wales and Scotland are suffering from advanced and extensive tuberculosis with widespread caseating lesions in subcutaneous tissues and in the viscera which contain large numbers of acid-fast bacilli. These bacilli have produced fatal disease in guinea-pigs and non fatal in rabbits rendering both animals tuberculin-positive, they are therefore certainly tubercle bacilli but whether they are of the bovine or some other type is not yet known. To those accustomed to regard tuberculosis as a disease of domestication in animals its prevalence among inhabitants of wild uplands and moors will seem positively incongruous. There are some puzzling features in this discovery which make it seem unwise to draw any conclusions at this stage. It is difficult to see how such a disease as tuberculosis could be responsible for a periodic rapid slaughter of animals with an intervening steady rise in population moreover voles supposedly suffering from this epidemic disease have been examined before without this very striking and obvious condition being found. On the other hand there is the fact that 134 voles trapped in seven different localities have been found with tuberculosis if the disease is really widespread in such areas there is even a possibility of appreciable contamination of water supplies and the presence of similarly infected voles on farm lands would have to be considered a serious factor in the spread of tuberculosis among cattle. Extensive field work will be necessary to determine the distribution and frequency of the disease and with this information and the identification of the type of tubercle bacillus which is all important it will become possible to decide whether these disturbing speculations have any further basis in fact. In the meantime we may reasonably ask ourselves whether disease in animals is being adequately studied in this country. It might have been supposed that the common diseases of our principal fauna were well known but we may now wonder whether there are not other species especially among wild animals and perhaps birds whose entire pathology is an unexplored

ROBERT PHILIP AND TUBERCULOSIS

This year marks the half-century since Robert Philip established in three small rooms at 13 Bank Street Edinburgh, "The Victoria Dispensary for Consumption," and thus opened a campaign against the ravages of tuberculosis a campaign that has been pursued tenaciously for many years and found support abroad earlier than in Philip's own country. His contribution to the control of tuberculosis is appreciated to the full only when the appalling conditions that existed fifty years ago are realized. In this country tuberculosis showed a greater mortality than any other disease and the sufferers were excluded because of the chronicity and infectious character of the disease and no other provision for treatment existed except such as could be provided in the Poor Law institutions which were both feared and detested. Robert Philip realized that the control of tuberculosis was not merely a medical problem but that it involved social and economic and even political considerations as important as the medical aspect. And his conception of the work of the tuberculosis dispensary must have been founded on a prophetic consciousness of the additions which were to be made to the then inadequate knowledge of the disease for contact examination without radiology could only have removed the gross evils of the infection. Perhaps this is partly the reason why so many years passed before the example set in Edinburgh was followed elsewhere in Great Britain. The first tuberculosis dispensary in England was established at Paddington by a voluntary body in 1909 though by 1905 there were already fifty in France all based on the principles laid down by Philip. When finally the State decided to take over the control of the disease in Great Britain it was able immediately to adopt a scheme whose details had been thoroughly worked out. Much of the spade work in the control of tuberculosis had already been done by the (voluntary) National Association for the Prevention of Tuberculosis founded in 1898, and in this work, too, Philip had played a conspicuous part. But perhaps the most important thing is the international influence Sir Robert Philip has exercised through his numerous publications and attendances at congresses in persistently bringing before responsible authorities the evil results of the disease and the methods that can be used to combat them. Finally his appointment in 1917 as the first professor of tuberculosis in this or any other country which has encouraged the founding of four similar chairs in Europe since must have done much to further the teaching and study of the disease. An article in the May issue of the *Edinburgh Medical Journal* describes the Edinburgh Tuberculosis

Scheme from its foundation fifty years ago and the part played by Sir Robert Philip. A list of his contributions to the literature of tuberculosis is added. The article concludes "In their own many and different ways, both at home and abroad, governments, universities, medical societies and colleges, tuberculosis associations, and old students have shown their appreciation of Philip and his life-work. It is only fitting that the Edinburgh Medical School which he has served so well in many capacities should on this fiftieth anniversary place on record its tribute." We feel that we can do no less.

INTERNATIONAL ABOLITIONIST CONGRESS

A main if not the chief function of the forty seventh International Abolitionist Congress, held here on May 20 to 22 (writes our Paris correspondent), was to strengthen the hand of the French Government whose Minister of Public Health M. Henri Sellier, has drafted a most ambitious Bill dealing with venereal disease, prostitution, and allied subjects. This congress had the avowed support of powerful sections of the community but it is no secret that important forces in the fighting services look askance at the prospect of the suppression of the regulation of prostitution in brothels under more or less official medical supervision. It is significant that Cardinal Verdier, Archbishop of Paris, was a member of the Comité d'Honneur and it would seem that the Church is adopting a more call a-spade attitude in this field than it did only a little while ago. It may be noted that the present system of regulation of prostitution in France dates from the Revolution and the First Empire. Before that time prostitution was not regulated in any official sense, and was, indeed liable to severe penalties. Even now the legal status of tolerated brothels in France is very precarious, and in any given community it is the mayor who has it in his power to smile or frown on such undertakings. He may authorize or forbid them and if he has authorized one he may change his mind and close a brothel without having to pay any compensation, the law having hitherto given no official sanction to the public brothel to enjoy any of the rights of commerce. In fact however petted and pampered such institutions may be in practice they are in the eyes of the law still only tolerated. Hence the term 'maison de tolerance'. The landlord of a house used as a maison de tolerance may turn his tenants out as promptly as he likes and with no fear of prosecution for legislation dealing with rentals etc. does not apply to brothels. In French law every contract with an immoral element is considered as void and null. The legal vulnerability of even the most regulated of brothels and the legal powers possessed by mayors are two features which the enemies of the regulation of prostitution have done their best to bring to the attention of the public at this well attended Abolitionist Congress in Paris. One of the most interesting reports presented was by Dr. Hermans, secretary of the Netherlands National League against Venereal Disease. The lesson of Holland in this respect would seem to be that a well-organized voluntary association is remarkably effective even when unaided by coercive State measures.

THROMBOTIC NON-BACTERIAL ENDOCARDITIS

In 1923 Libman¹ suggested that endocarditis could be classified as rheumatic, syphilitic, acute bacterial, sub-acute bacterial, and indeterminate. In the following year he² separated from the indeterminate class some cases having features in common which he called "atypical verrucous endocarditis". Gross and Friedberg³ who have described the morphology of the rheumatic heart in much detail, have also been investigating this indeterminate group and have recognized a form of endocarditis distinct from the atypical verrucous type, which they term "non bacterial thrombotic endocarditis". At the Mount Sinai Hospital 150 cases have been diagnosed post mortem as indeterminate endocarditis during the last twenty years. Of these Gross and Friedberg excluded over a hundred as there was a possibility of an active rheumatic or bacterial infection, or details were incomplete. There remained, however, nearly fifty cases which showed a characteristic endocarditis and could be subdivided into three main clinical groups. In the largest group were those with chronically deformed valves, usually of rheumatic origin, the patients had died of cachectic or of infectious diseases but there was no microscopical evidence of active rheumatism. In these cases yellowish vegetations of somewhat friable nature were found on the valves; they were larger than rheumatic vegetations and sometimes were polypoid similar to those in bacterial endocarditis. They occurred either on the closure line of the valve cusp or on the corpora arantia and never involved the mural endocardium or valve pockets. The mitral valve was affected in almost every instance and the other valves less frequently in the order corresponding with the valvular involvement in rheumatism. Microscopically the vegetations consisted of agglutinated blood platelet thrombi showing varying degrees of organization. There was practically no cellular reaction in the valve or endocardium, apart from those lesions which Gross⁴ has described in inactive rheumatism. Cachectic or marasmic vegetations are well known but the importance of the recognition of this thrombotic group by Gross is the distinction that can be made between them and terminal rheumatic or bacterial vegetations. The second clinical group consisted of three young women suffering from severe thrombocytopenic purpura; the course was acute and pyrexial but repeated bacteriological investigations were negative. At necropsy thrombotic endocarditis was present together with splenomegaly; microscopically there was in addition to the valvular changes widespread change in the smaller vessels characterized by hyaline or granular thrombi which occluded the lumen and in some instances were organized. In the third group the onset of the illness (also in young women) was marked by polyarthritis which involved both large and small joints. There was persistent fever and polysclerosis. Blood cultures were sterile and death resulted from cachexia and increasing anaemia. The pathological changes consisted of widespread

endothelial proliferation in small vessels producing endarteritis and endophlebitis in some cases this was associated with obliteration of the lumen by hyaline thrombi and in one there was a necrotizing arteritis somewhat resembling that found in polyarteritis nodosa. Further, there were adhesions obliterating the serous cavities and thrombotic endocarditis. Gross and Friedberg do not suggest that the valvular lesions played any part in the clinical course or that they are the essential part of the syndrome but the lesions are obvious post mortem and are a common feature in all three groups. The second and third groups have clinical points in common and also resemble both clinically and pathologically the cases of disseminated lupus erythematosus described by Baehr, Klempner and Schiffrin¹. It would appear that they are clinically related on the one hand to polyarthritis and on the other to polyarteritis nodosa, whatever their aetiology may be. A more detailed study of these obscure "endothelioses" is overdue, and the work of Gross and Friedberg gives a useful foundation for it.

OPIUM SMOKING IN THE FAR EAST

From the time of the Hague Opium Convention of 1912 efforts have been directed to put down opium smoking in the Far East. Gradual but effective suppression of the trade was contemplated twenty-five years ago, but the extent of illicit traffic was reported to have so hampered attempts at suppression that in the Geneva Conference of 1925 it was resolved to put off further measures until a Commission about to be appointed, should report that smuggling was under control. Even then a period of not exceeding fifteen years was mentioned as a reasonable interval before suppression could be effectually carried out. As the result of the Commission's report a conference of representatives of the Powers concerned was held at Bangkok in 1930 and an 'agreement for the suppression of opium smoking in the Far East' was signed. This agreement came into force on April 22 last and as it has been ratified by all the Governments parties to it some progress may now be anticipated. Great Britain for the Malay States and Hong Kong, the Netherlands for the Netherlands Indies, France for Indo China, Portugal for Macao, Japan for Formosa and Kwantung, Burma and Siam are the parties concerned. The agreement sets up Government monopolies for retailing and distribution of prepared opium, prohibits smoking under 21 years of age and provides for severe penalties for offences. The final act recommends licensing, rationing, and registration of smokers, measures for facilitating the cure of opium smokers, and research into the physiological and psychological effects of such smoking. Annual reports are to be made to the League of Nations and special opium revenue accounts are to be kept. In accordance with the findings of the Commission of Inquiry, the need for limitation of poppy cultivation is to be kept in view, and indeed this is a question which it is understood will shortly be the subject of a fresh international Conference at Geneva.

INTER-DEPARTMENTAL COMMITTEE ON ABORTION

The Minister of Health's statement in the House of Commons about the newly appointed Inter-Departmental Committee on Abortion was briefly reported in our Parliamentary Notes last week. The chairman of the committee is Mr Norman Birkett, K.C., and the other members are Dame Lucy Baldwin, Lady Ruth Balfour M.B., Sir Comyns Berkeley, consulting obstetric and gynaecological surgeon to the Middlesex Hospital and chairman of the Central Midwives Board, Mr H. A. de Montmorency, Dr T. Watts Eden, consulting obstetric physician to Charing Cross Hospital, Lady Forber, who as Dr Janet Lane-Claydon was engaged in medical research for the Ministry of Health, Sir Rollo Campbell Graham, chief Metropolitan magistrate, Dr G. C. M. McGonigle, medical officer of health for Stockton-on-Tees, Sir Ewen Maclean, president of the British College of Obstetricians and Gynaecologists, Captain M. P. Pugh, prosecuting solicitor for Birmingham since 1924, Mr W. Bentley Purchase M.B., coroner for the northern district of London, Mr C. D. C. Robinson, Mrs Ernest Thurtle and Lady Williams, wife of Sir Rhys Williams Bt. The committee's terms of reference are "To inquire into the prevalence of abortion and the present law relating thereto, and to consider what steps could be taken by more effective enforcement of the law or otherwise to secure the reduction of maternal mortality and morbidity arising from this cause." Communications relating to the inquiry should be addressed to the Secretary, Committee on Abortion, Ministry of Health, Whitehall, S.W. 1.

RESEARCH DEFENCE SOCIETY

The eleventh Stephen Paget Memorial Lecture on "What Research Owes to the Paget Tradition" will be delivered by Professor G. Grey Turner D.Ch., M.S., F.R.C.S., at the annual general meeting of the Research Defence Society at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Tuesday, June 15, at 3 p.m. when the chair will be taken by the president, Lord Lamington, supported by Sir Arthur Stanley, chairman of committee, and Professor A. V. Hill F.R.S. vice-chairman of committee. Tea and coffee will be served after the meeting, and visitors will be welcomed.

Professor James Young D.S.O. M.D., has been elected chairman of the medical advisory board of the British Social Hygiene Council in succession to Sir E. Farquhar Buzzard Bt., K.C.V.O. M.D.

The National Hospital for Diseases of the Heart has arranged for the St. Cyres Lecture for 1937 to be delivered in the Barnes Hall of the Royal Society of Medicine, 1 Wimpole Street, W. on Thursday, June 10, at 5 p.m. The lecturer is Dr Ch. Laubry, professor of cardiology in the University of Paris, and his subject "Considerations Pathogeniques et Cliniques sur les Rythmes de Galop."

LEAGUE OF NATIONS HEALTH PROGRAMME

THE NEXT THREE YEARS' WORK

A session of the Health Committee of the League of Nations which directs the health work of the League and in particular the Health Section of the Secretariat, was held from April 26 to May 1 under the chairmanship of Professor Parisot, director of the Institute of Hygiene at Nancy. Representatives of seven countries attended, the British representatives being Dr M T Morgan and Dr N M Goodman of the Ministry of Health. The main work of the Committee was to approve the next three-years' programme (1937-9), largely a continuation of the work already carried out.

Epidemiological Intelligence

The service of epidemiological intelligence and public health statistics includes the work of the Eastern Bureau at Singapore, which is in weekly communication with the ports of Eastern countries, and the intelligence service at Geneva, from which are published figures relating to communicable diseases and births and deaths from all countries where such data are available. These services are to be maintained and developed. The international list of causes of death is now being revised by a technical committee with a view to making the public health statistics of different countries internationally comparable. A study was started last year, and is to be continued, with the object of presenting in statistical form the state of public health in reference to 'vitality,' meaning fertility and population, and "health," meaning mortality, morbidity, and the incidence of physical and mental defects, reference also being made to geographical, social, and economic environment and the various medical and sanitary activities of the community concerned. Material regarding maternal mortality and welfare is being collected in a number of countries to form the basis of a double report, one part dealing with the organization of welfare services and the other with maternal mortality and morbidity and their causes.

Biological Standardization

Another governmental conference on biological standardization similar to that which met in Geneva in 1935 is projected for 1939 if the experimental research work now being done internationally in this field is sufficiently advanced. Forty-one countries, including Great Britain, India, all the Dominions except New Zealand, and the United States have adopted or are about to adopt some or all of the international biological standards and thirty-one countries, including those just mentioned except Australia, have created or are about to create national centres to hold and distribute the international standards. The task of the central institutes at Copenhagen and at Hampstead will thus be simplified though it is anticipated that the Copenhagen institute will as in the past have to supply international sera to the great majority of national centres.

Several questions in the field of serology need to be reviewed from the therapeutic and the practical aspects. Changes in the international standards for tuberculin and staphylococcus antitoxin fall to be considered. A new field recently explored is that of anti snake venom serum. The problem of standardization here is so wide and complicated that it is considered wise at present to limit the study to anti viper serum and to the European viper. The Copenhagen institute is in correspondence with the European laboratories producing anti viper serum (Milan, Paris and Zagreb) and is endeavouring to work out methods of standardization. At the same time the assistance of institutes in Eastern countries is being secured with a view to the standardization of anti-cobra serum.

Pharmacological standards, as well as those for vitamins and sex hormones come within the next three year programme of the Biological Standardization Commission.

Malaria Leprosy Dangerous Drugs

The Malaria Commission is to take in hand the preparations for another governmental conference on quinine and kindred febrifuges, to be held not earlier than 1939. This conference will also take up the question of synthetic drugs. It is proposed that the League should organize meetings of experts from the various institutions for the study and prevention of leprosy, including the British Empire Leprosy Relief Association, with the object of taking up certain definite questions so that the main effort may always be concentrated upon some matter of outstanding importance.

On the proposal of the United States Government the Health Committee will proceed, jointly with the Office Internationale d'Hygiène Publique (an autonomous body, but related to the League by virtue of the fact that its permanent committee is the General Advisory Committee of the League's Health Organization), to study a new phenanthrene derivative of morphine—namely, desomorphine—which appears to be particularly harmful by reason of its toxicity and habit forming properties. The Health Committee has also undertaken to study the various methods of treatment of addicts in European and North American countries.

Housing and Physical Fitness

Among the subjects which have lately occupied the attention of the Health Organization, and are included in its three-year programme, are housing, physical fitness, and nutrition. A conference on rural hygiene in Eastern countries is to be held at Bandoeng, Java, in August next at the invitation of the Netherlands Government, and a similar conference for the American continent is mooted for 1938, to be held in Mexico City.

Arising out of the first (European) conference on rural hygiene in 1931, the study of housing has been continued, and the committee recommends a number of subjects for the attention of the experts who will be meeting during the present year. With regard to physical fitness, it is considered that the work in this field can only be adequately pursued by appointing a committee of physiologists to formulate the scientific basis of rational physical education adapted to different ages. The International Labour Office has already set up a committee with a similar reference, and the two bodies will collaborate.

Nutritional Surveys

A Technical Commission was appointed by the Health Committee in 1935 for the development of the League's work on nutrition which came forward so prominently at the Assembly of that year, and this body has now recommended a list of subjects for further study. The first of these is the assessment of the nutritional state of children. A consultation of physiologists and paediatricians held in December last recommended various types of survey, one being applicable to the state of nutrition of large groups of children and limited to a record of physical appearance, weight, and height and another to smaller groups but involving more extensive tests including a thorough medical examination as well as an economic social and dietary survey. A third type of inquiry is also proposed aiming at a study of the disturbances affected the body owing to a quantitatively and qualitatively deficient diet. Several of these different types of study are being carried out in Belgium, France and the Netherlands; others are contemplated in Sweden, Czechoslovakia and Austria and will deal with 50,000, 10,000 and 20,000 children respectively.

It is also considered that a general study should be made of the extent to which diets in common use fall below it.

WILLIAM EVANS EARLY DIAGNOSIS AND TREATMENT OF HEART FAILURE

FIGS 1 and 2.—Teleradiographs showing displacement of heart in failure. Fig. 1 before treatment shows greater displacement of heart from right-sided hydrothorax than Fig. 2, after treatment

FIG. 3 and 4.—Teleradiographs showing pulmonary congestion in heart failure. Characteristic hilar shadows appear in both skiagrams, but are less conspicuous in Fig. 4 taken after three weeks rest, than in Fig. 3 taken before resting

WILLIAM EVANS EARLY DIAGNOSIS AND TREATMENT OF HEART FAILURE

FIGS. 5 and 6.—Teleradiographs showing relief of pulmonary congestion from heart failure by rest in bed along with a diminished fluid intake and salyrgan administration. Fig. 5 was taken before treatment, and Fig. 6 one month after commencement of treatment, in a case presenting hypertensive heart failure.

FIGS. 7 and 8.—Teleradiographs showing arterio-venous aneurysm. Heart diminishes in size and pulmonary congestion is relieved following resection of aneurysm. Fig. 7 taken before operation. Fig. 8 taken one month after removal of arterio-venous aneurysm of lower third.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 5 1937

CAPITATION FEE: COURT OF INQUIRY PROCEEDINGS

The Court of Inquiry into the insurance capitation fee opened its proceedings at the Ministry of Health on Wednesday, May 26. Lord Amulree presided, and the other members of the tribunal were Mr Thomas Howorth and Mr D H Robertson with Mr E H Phillips, secretary.

The Insurance Acts Committee of the British Medical Association was represented by Dr H Guy Dain who presented the case, together with the following: Dr D E Dickson (chairman of the Panel Conference), Dr J A Brown, Dr D G Greenfield, Dr E A Gregg, Dr C F T Scott, with Dr G C Anderson and Dr C Hill (respectively Medical Secretary and Deputy Medical Secretary).

The case of the Ministry of Health and the Scottish Office was presented by Mr T D Harrison, who was supported by the following: Mr J Chown, Dr Ferguson, Mr E Hackforth, Mr T Lindsay, Mr F F Marchbank, Mr A W Neville, and Miss M E Ritson.

Other parties which put in an appearance included the Medical Practitioners Union, the Joint Conference of Friendly Societies, and the National Association of Insurance Committees.

First Day

Opening Proceedings

LORD AMULREE said that the Court proposed to hear first the evidence of the Insurance Acts Committee, then that of the Medical Practitioners Union, after which the case of the Ministry of Health and the Secretary of State for Scotland would be presented. There would then be opportunity for other bodies to make comment, and a general reply would be made.

DR GORDON WARD made a protest on the ground that the Ministry had refused to circulate its memorandum generally beforehand (he understood that memoranda had been exchanged between the Ministry and the British Medical Association but these had not been generally available) and that the Minister was not to place his evidence before the Court first. He also objected that between the issue of the terms of reference and the date on which memoranda of evidence had to be submitted only thirteen days were allowed to elapse, two of which were public holidays. LORD AMULREE said that the protest would be noted but with regard to the order of procedure everyone would have an opportunity of stating his case, and there would be opportunity for a general reply.

Some preliminary argument then took place between Dr DAIN and Mr HARRISON (for the Ministry) with regard to the periods taken as relevant for the purpose of comparison. Dr Dain pointed out that the evidence given before the previous inquiry in January 1924 referred to the conditions obtaining in 1922, whereas the Ministry in its present memorandum had taken 1924 as the basic year.

LORD AMULREE said that the position was that in 1924 the available evidence related to facts ascertainable for 1922, just as the position to-day was that although the Court was sitting in 1937 the data available were those obtaining in 1936. On that understanding Dr Dain proceeded to open his case.

The Committee's case and the case of the Ministers with the rejoinders were published in the *Supplement* to the *British Medical Journal* of May 29.

Insurance Acts Committee Case

DR DAIN, in opening the case for the Insurance Acts Committee, said that in preparing its memorandum the Committee had been concerned with the changes which had taken place since the previous award in 1924. These changes came under two headings: economic changes which affected the population as a whole, including doctors, and changes in the work and responsibility of insurance practitioners. When they approached a decision on a matter like the capitation fee, in which a very large number of doctors were concerned on the one hand and the Government of the country on the other, it was almost impossible to settle by agreement between the parties, and so it became necessary to ask for a tribunal consisting of persons not connected with either party to hear the arguments and determine the result.

In 1920 a board of arbitration fixed the fee at 11s. Economic conditions altered rapidly at that time, and two years later practitioners accepted without further argument a reduction to 9s 6d. But in 1924 the question was again argued before a Court of Inquiry, which awarded 9s, the figure reflecting the changed economic conditions of the country. The items of service per insured person which the profession claimed to be rendering at that time numbered 375 or, according to the Ministry, 35. A great increase had taken place since then in the amount of work required on behalf of insured persons, and a request for a reconsideration of the fee was on the point of being put forward in 1930 and 1931, when the economic crisis occurred, as a result of which the medical profession consented to a 10 per cent deduction partly removed in 1934 and finally in 1935. In the beginning of 1937 the Committee approached the Minister and it was agreed that the matter should go to the present Court.

At the hearing in 1924 the profession were considerably disadvantaged on two points. They had not a sufficient volume of figures on the cost of practice or on the number of services given. After the award in that year steps were taken to remedy that deficiency, and it was hoped now to satisfy the Court that the figures put forward in the memorandum were substantially correct and not to be really disputed. On the economic question generally it must be remembered that the number of insured persons in proportion to the whole population was increasing so that this service absorbed a greater part of the work which fell to the doctor's lot. A doctor in any large practice must depend to a greater extent than formerly upon his insurance work. There had been

a large increase in the proportion of doctors to the population since 1924, and it was now practically impossible in most areas for a man to be in practice without undertaking some insurance work

Economic Factors

Passing to economic factors that concerned doctors, Dr Dain drew attention to the appendix by Professor Bowley, who had estimated that the fall in cost of living for middle-class persons had been from 7 to 10 per cent. since 1924. The Ministry had taken a different set of figures, and had suggested that the deduction from the doctor's capitation fee on this account should be in the neighbourhood of 5d, computed, properly and fairly, on the doctor's net income, not his gross income. This corresponded more or less to the 7 per cent. of Professor Bowley, so that there was no great disagreement on that point. He added, however, that as the fee fixed by the Court would date from 1938 it should be borne in mind that a rapid increase in the cost of living was now taking place, and was likely to go further before the end of the present year.

A large volume of figures had been collected with regard to practice expenses. The practice taken into consideration by the Court in 1924 was that of a doctor who dispensed for his private patients and not for his insured, and it was estimated that his practice expenses would be 25 per cent. of his receipts. Such figures as were then available had been compiled partly over war years, and were subject to a number of serious criticisms. But the figures collected since then showed a very steady average for the various kinds of practice, and the comparison which should be made to-day on that basis showed that in place of the 25 per cent taken in 1924 33 or 34 per cent should be taken to-day. These figures had been collected from doctors willing to submit their accounts, in many cases audited by professional auditors, and in other cases accepted by the income tax inspector. They included all kinds of practices, and they showed that practice expenses should be considered as representing one third instead of one fourth of the gross income. Copies of the original accounts could be seen by the Court.

Dr Dain next dealt with the way in which the expenses of practice were made up. The Ministry had assumed that 75 per cent. of the expenses came under the head of travelling, but the expenses included part rent and rates, service heating and lighting telephone repairs and locumtenents as well as travelling. Travelling accounted for approximately one-third of professional expenses. On the other items there had been very little change. If some of them such as telephone costs had gone down others like domestic service had gone up, and the cost of locumtenents was greater.

The Ministry had suggested that there had been a saving of 35 per cent in the cost of travelling since 1924. The Committee's assessment was very different and he proposed to call motor experts to give evidence on that point. Moreover the distances travelled had increased on account of the population having moved away from dense areas into the new housing estates. As a matter of experience they found that they had more miles to travel. The increasing number of doctors in practice had reduced the income of the individual doctor, and yet to-day he was travelling further for the same money. In the Ministry's case it was suggested that the doctor had economized in travelling by reducing the horse power of his car but the only evidence offered was the enormously increased sale of smaller motor cars. He suggested that this had nothing to do with doctors or their practices but was the result of the altered type of person who purchased a motor car to-day as compared with 1924. Evidence on this point would be offered. The saving in the cost of travelling was represented only by a matter of a penny or less in the capitation fee.

Services Rendered to Insured Persons

Dr Dain next dealt with the service rendered to insured persons. Immediately the previous Court was over the Committee instituted a new method of collecting statistics. The method was set out in the rejoinder to the Ministry's memorandum. Areal documents were available showing the number of volunteers. The principle was to ask for volunteers from every area to the proportion of 10 per cent. Although for the years from 1924 to 1930 the samples were not up to the requirements so far as numbers were concerned, in later years it had been possible to get the requisite sample in all areas. The result was a day to day record of the work done. It included the whole of the doctor's work, not just a proportion of it. Further, it extended over a series of years. Although the figures did not relate to any particular practice over the whole of the twelve years, 3,000 practices had contributed their figures for one year or a period of years. Visits and attendances varied considerably from one year to another, an indication of the variation in sickness incidence. Great unfairness might result from comparing any particular two years. In 1927, for example the attendances were 503 per insured person, and in 1931 they had fallen to 475. If these were the only figures available it would be taken that the doctors were doing less work, but the succeeding years showed that this was not the case. The Committee offered the Court a set of figures from which it was fair to deduce the amount of work done, not in one year but over a period. There was a great discrepancy between these figures and those of the Ministry, and the Court would have to satisfy itself as to which were correct. There were one or two factors which supported the contention that since the 1922 figures were prepared there had been a substantial increase in work. This was shown by the increase in the number of certificates and prescriptions issued. The Ministry's figure of 4.6 prescriptions per insured person suggested that the Committee's figure of five items of attendance was reasonably accurate at any rate more nearly accurate than the Ministry's figure, which would make it appear that each insured person got more prescriptions than visits or attendances. If an insured person went five times a year to his doctor it was not unreasonable to expect that he might get four prescriptions issued, for a patient did not get a prescription at each visit or attendance. The prescriptions must be less rather than more than the number of attendances.

The Ministry's figures started from the year 1924 covered thirteen years and 600 practices and in each case only a proportion of the practice was reckoned. There must be a number of sources of error in figures taken in that way. The count was taken months after the event and those of them in practice knew how the doctor's list was in a continual state of change. In the Committee's computation they had asked practitioners to count up to the end of the year the attendances they rendered, and the result corresponded at any rate to a fairly steady figure. Such changes took place in the lists that the value of any count taken some time afterwards was seriously vitiated.

After dealing with various matters relating to the method of computation Dr Dain submitted that on the increase in the amount of work practitioners could properly substantiate a claim for an increase of one third on the capitation fee.

Nature of Service

Passing to the nature of the work done he said that those who spoke for the profession had always taken the view that the service given should be a full general practitioner service and the best that the doctor could provide. When as not infrequently happened some new method of diagnosis or treatment arose they believed that the practitioner should not say that this was not before the Court of Inquiry when it made the last award and

ought to be regarded as an extra, they had maintained that such new methods should be absorbed into the service and given to insured persons in the expectation that the next time the Court was assessing the capitation fee it would bear in mind that practitioners were in fact doing work which did not come into the original calculations. He pointed out that to-day no woman expected to go through her confinement without being examined ante natus, and although the importance of ante natal examination was appreciated by the profession in 1924, the public did not appreciate it. Methods of diagnosis had extended very much during the last ten years. There had been, and still was, an increasing interest in the causes of disease, and this had led to more work.

The Ministry rather belittled the work that the insurance practitioner was called upon to do, referring somewhat slightly to 'catarrhal diseases and rheumatism'. It had taken unfortunate examples, because, in fact, the work done on catarrhal conditions—the taking of swabs, the examination of antrums and sinuses—and in rheumatism—bacteriological examination of stools and other procedures—all entailed very much more work than a few years ago because then they were not so familiar with the causes of the complaints. He submitted that the Committee had not in the least exaggerated the importance of the change in the nature of the doctor's work, if anything it had been understated. A change in the nature of illness had to be noted. It was not only bus drivers who showed an increased incidence of gastric and duodenal ulcer—he believed this applied over the whole population. There were other conditions which were on the increase, among them nervous strain due to pressure of work and repetition work in factories.

References to Hospital

On the hospital question, of which a point was made in the Ministry's case it must be borne in mind that the insurance service was a general practitioner service only and did not include specialist service—pathological and x-ray services and so on. If it was true that practitioners sent a large number of their patients to hospital, let it be remembered that they were sent there for bacteriological tests, x-ray examination, or specialized consultation, and, the examination having been made, the patient came back to the insurance doctor for treatment. Practitioners carried out the treatment for gastric ulcer after the x-ray examination, for pernicious anaemia after the blood tests had been made, and so on. They were sending large numbers of patients to hospital, not to the diminution of their work, but rather to increasing the value of it. If the practitioners could do all work which the Ministry suggested they should do they would be right in asking not for a modest 12s 6d., but for a much larger sum. As an evidence of the increased amount of work, there were now large numbers of people with diabetes or pernicious anaemia who were only alive because of the treatment they got week in and week out, month in and month out. These people remained constantly under treatment.

Finally, Dr. Dain touched on the question as to the admission of juveniles—those who had left school at 14 plus and had gone into employment. It must be borne in mind that the Ministry first offered a capitation fee of 6s for these persons, then 7s 6d., and at last talked over with the Committee the possibility, under certain conditions, of applying to them the ordinary capitation fee. To turn round now and say that 4s 6d. would be a fair fee for these young persons was not a very reasonable attitude. There were one or two points to bear in mind. The number of these people was a steadily decreasing one and was liable to sudden extinction should any Government raise the school leaving age to 16. In that case they would not come into insurance any earlier than now. That was one possibility which he hoped the Court would not entirely ignore. The Ministry's case was that the inclusion of this group of juveniles reduced the average

age of insured persons. That was true, but the reduction was by no substantial amount when one put one million against eighteen millions, and moreover, it was a decreasing amount because, with the declining birth rate, the number of these people would gradually shrink. On the other hand the age of the population was gradually increasing. Figures had been obtained from an expert which showed that the mean age of the population was 31½ years, and that by 1950 it would be 36 years.

To summarize the case, the Committee appreciated that owing to the reduced cost of living 5d. might be deducted from the capitation fee, and a further halfpenny or penny on account of the reduction of the cost of transport. On the other hand increased practice expenses justified an increase of 9d., and the increase in the items of service given to insured persons an increase of 3s 3d. This resulted in the 12s 6d. which, the Committee submitted, should be paid to the insurance practitioner.

Travelling Expenses Evidence

Mr. H. SCOTT HALL, a motor engineer, consultant in motoring economics, and a motoring journalist, gave evidence on his report, which was included in the rejoinder by the Insurance Acts Committee, on the question of car costs. He explained how the figures given in that report had been arrived at. Asked by Mr. Harrison whether there was not a big difference between the depreciation figures in 1924 and in 1937, he said that the difference arose from the fact that the actual market values of cars did not drop with anything like the same rapidity in 1924 as they did to-day. Asked how much longer a car lasted in 1924 than in 1937, he said that broadly speaking his opinion was that a car was used for a year or a year and a half longer in 1924. The reason for the more frequent change had to do to a great extent with fashion, and with the fact that, in view of the generally good appearance of cars on the roads, the doctor could not afford to go about in a car not in good condition.

The point was put to the witness by Mr. Harrison that the more frequently a doctor changed his car the lower would be his maintenance costs in the sense of repairs and overhauls. Mr. Scott Hall replied that for the first 24,000 miles maintenance should mean no more than periodic decarbonization, occasional adjustment and greasing, and possibly, depending on the nature of the district, re-lining of the brakes. He said that there was no economy in maintenance effected by selling a car the first year. He also stated that the 10 h.p. car was not used to any great extent by doctors.

Mr. PATON, director of Mann Egerton and Co., Ltd., consulting engineers to the Medical Insurance Agency since 1933, put in a statement concerning fifty consecutive sales of new cars to doctors in the Greater London area from June 1935. The average value of the car purchased was £251, and the average horse power was 14.6. He had got out corresponding figures for fifty consecutive sales from January 1, 1934, when the average value of the car purchased was £324, and the average horse power 13.03. In both lists he had eliminated consultants so far as he knew them. These were new cars, not second-hand, but doctors did frequently purchase second-hand cars preferring a higher grade of second-hand to a cheap new one. The guarantee for a second-hand car was three months only, and therefore the maintenance charges began almost at once, whereas a new car had a clear year.

In reply to a member of the tribunal, who asked why the average horse power of doctors' cars should be relatively high, the witness replied that the average doctor did not like a 10 or 7 h.p. car, he preferred from 14 to 18 horse power. Many doctors, especially in the London area now ran American cars, which brought up the average a little. The young practitioner might start with a 7 or 10 h.p. car but he liked to change as soon as he could to something better. Questions of comfort and prestige he supposed, entered into it.

Mr HARRISON for the Ministry said that Mr Paton's figures were really for suburban London. It would be interesting to have evidence from industrial areas like Leeds and Birmingham on that point.

Dr DAIN said that the Committee was contesting the Ministry's case that there had been a very large drop in the cost of travelling, but it was extremely difficult to provide evidence if it was required from different parts of the country. The sale of cars in large provincial cities would be spread over an enormous number of agents.

The I.A.C. Statistics

Before the Insurance Acts Committee case concluded Dr Dain was asked certain questions by Mr Harrison for the Ministry.

Did the doctors make their returns knowing the purpose for which they were to be used?—Yes, they knew they would be used for this purpose at some future time.

How did the Panel Committee get the 10 per cent of practitioners who made returns?—They called for volunteers.

They asked everybody and took what they could get?—If you like to put it in that way.

There was no attempt to select 10 per cent of people in typical practices?—Over the whole country, no, in areas where there were more volunteers than required some selection would be made.

You made no attempt to select so as to secure industrial semi-industrial rural practices large and small practices and so on?—We have them classified into rural and urban.

In your system there is nothing to prevent the whole of the returns from a particular area relating to one type of practice?—There is nothing to prevent it, but it did not happen. We can say that.

In recording attendances may not a doctor interpret it too widely and tick up an attendance every time he sees an insured person on whatever subject? Insured persons come to their doctors on other matters than health, say for a signature for a passport?—That is not a professional attendance on an insured person. I cannot guarantee that such things have never been done, but I cannot conceive a practitioner recording it as an attendance on a patient.

Supposing a doctor visits a patient in the morning and tells him to come to the surgery at night for a certificate, would that count as a visit and an attendance?—Certainly not. More over, if a patient is ill enough to require a visit, he is not well enough to come down for the certificate the same day. Doctors usually have their certificates with them.

Is a call at a branch surgery properly a visit? Is it not an attendance?—In outlying villages these have been counted as visits. They require travelling on the part of the doctor outside his immediate area.

If his practice is so extensive that he has to have a branch surgery for the convenience of himself or his patients, a patient's call there should not count as a visit?—Well, it is counted as a visit, it affects the statistics very little.

In reply to members of the tribunal Dr Dain said that the average of 53 items of service per insured person per annum was not the average of a very wide range. The highest figure would be about 7 in a thickly populated area. He also said that the computation of practice expenses did not include interest on capital or payment of income tax taken generally, the expenses were such as the income tax inspector would allow. They included the rent of the part of the house used for professional purposes. Lord Amulree said that they apparently included commission on debt collection, but there were no debts in insurance practice. Dr Dain replied that the whole expenses of practice private and insurance had been taken in order to compare with the figures presented at the previous inquiry. Practice expenses were the same for insurance as for other practice, except for dispensing and for such matters as debt collecting.

How do you account for practice expenses varying so much in individual cases?—It is difficult to give any idea. One man does all his work in one house, another has branch surgeries. One has an assistant and another has not. One may be economical in his practice, another more extravagant. It is the difference between one person and another.

What number of visits and attendances would be considered a reasonable day's work for a doctor?—We gave evidence on that before the last inquiry and we understood it was taken into consideration in the award made in 1924, so we have not come prepared to argue that point. We have directed our attention to changes which have taken place since the award.

Mr Harrison said that at the last inquiry it was mentioned that a doctor with a list of about 2,000 would have to see rather more than 25 patients a day.

Dr Dain mentioned that the figures for the first three months of the present year had been taken, during which time there was a fairly severe influenza epidemic, and if this period were added to the 1936 figures the average of attendances and visits combined would be raised from 5.13 to 5.23.

Case of Medical Practitioners' Union

Dr GORDON WARD said that the Medical Practitioners' Union had considered that the discussion on the capitation fee would take into account every relevant factor, not be confined to the narrow range of statistics. He asked whether he was at liberty to present the case on more general grounds. The Chairman said that the Court by its terms of reference could consider 'other relevant factors' relating to changes which had taken place since 1924. Dr Ward said that a memorandum had been prepared by the Union in more ample form than the restricted evidence so far given. The Chairman said that in the circumstances Dr Ward had better put the whole memorandum before the Court, but he hoped it would be relevant. Reference to pensions and other matters were somewhat outside the scope of the Court.

Dr Ward said that pensions could only be provided by raising the capitation fee, and that was a considerable point. He then proceeded to speak on the Union's memorandum. The memorandum he said had been circulated to the profession and in response 200 letters had been received supporting the views put forward. The Medical Practitioners' Union was a registered trade union, affiliated with the Trades Union Congress, the great majority of its members being insurance practitioners. To the Royal Commission in 1925 the Union put forward as the only proper basis for capitation the current value of the services rendered as on that date. He proposed to put before the Court the nature of the services rendered by insurance practitioners. The public believed that a doctor was essentially a wealthy man. He drove a car and had a large house, and people did not stop to consider that the car was part of his obligations and the house included his surgery. As to remuneration the average doctor in Glasgow made £8 a week from his panel and spent £3 14s in earning it. As for the doctor's duties, he was on duty every day of the year all day, and all night too except during his annual holiday. The doctor must bring to his work no mean ability. An extremely high grade of skill was required of him. It cost him a minimum of £1,000 and six lost years of wage-earning to qualify for his profession. On the top of an ordinary education had to be added a special education. When he had entered the profession he was required to keep himself up to pitch and fully cognisant of new methods of diagnosis and treatment. As an insurance practitioner he had a considerable burden of clerical work. After doing his own proper work he had to do the work of the approved societies.

Conditions of Service

The number of prescriptions issued in 1920 in England alone was 28 millions, and in 1935 it had risen to 51 millions. That indicated that the work the practitioner had

done must have increased very considerably. Figures for disablement told the same story. In 1920 disablement amounted to four million weeks and in 1933 to 14 million weeks. With regard to the attendances per head, he was willing to accept the I.A.C. figures as accurate but he wanted to put before the Court something in the way of supporting evidence. Accordingly he read a number of letters from members of the Union and others giving particulars of the actual work they did. As for the conditions of service, there was first of all, some question of prestige. It was felt by the medical profession that the official administration of the insurance service had done serious injury to the doctors' prestige, and his Union accordingly offered evidence of the attitude of the Ministry under various heads. In Ministerial publications insurance doctors were subject either to offensive patronage or a detailed setting out of their faults, showing an altogether wrong orientation of feeling and policy in the Ministry. He objected to the schoolmaster tone towards insurance practitioners in reports of the Chief Medical Officer of Health of the Ministry. One of the things against which the insurance practitioner had kicked most was the record cards a perpetual source of annoyance, though he agreed that the clinical record was valuable. Dr Ward also spoke of intensification of services, a thing which could not be shown in statistics. A point to be borne in mind was the large number of calls which came out of hours, especially now that telephone kiosks were everywhere and patients were tempted to ring up their doctor for trivial causes. It was supposed to be a rule that if a doctor was required for a visit he should be informed before 10 a.m. on that day. In the old days this rule was more or less followed, but nowadays it had been more or less allowed to lapse. Formerly patients called upon the doctor when they had what might be described as a legitimate illness but nowadays they came to the doctor for a chat when he did not want them. Again the suggestions made by the Press and by wireless on matters of health had led to a good deal of imaginary illness and accident proneness and had thereby increased the burden of the insurance practitioner.

On the question of discipline it ought to be remembered that insurance practitioners like other people, in due course grew old and their memories were affected. They became not so nearly 100 per cent efficient as they used to be. Any tolerable disciplinary scheme would make allowance for age and normal failings to which everybody was liable. In the discipline under the Insurance Act there was need for a better adjustment of the punishment to the crime. Again it was one of their old grievances that the Ministry was both judge and accuser.

Coming to the consideration of the basic fee Dr Gordon Ward referred to the scale of fees allowed for comparable services by the National Deposit Friendly Society, which offered the great advantage of extra fees for special services. Had no futile records had found no need for a complex disciplinary code and covered the supply of medicines as well as the attendances in the ordinary visiting fees. He entered upon a comparison between the society's fees and those under national health insurance.

Second Day

On the second day of the hearing Dr Gordon Ward continued his remarks. He mentioned that in some of the Press reports of the proceedings on the previous day the Court had been referred to as an arbitration. His Union did not regard it as an arbitration at all an arbitration meaning that the result was binding upon the contending parties. This was a court wholly appointed by the Government.

Lord Amulree: It is a Court of Inquiry. It is not an arbitration in a technical sense.

Dr Ward: I cannot say what "a technical sense" means.

Continuing Dr Ward said that the Union put forward a case for a capitation fee of 13s 6d. But it felt that

the final capitation fee must cover more than that, as it ought to remedy the unsatisfactory conditions under which the service was given. It proposed that insurance practitioners should have 'promotion' at intervals, signified by an increase in pay, the promotion corresponding to what took place in the Civil Service. For every three years of completed service an insurance practitioner should be entitled to an increase of sixpence per head for each person on his list. As a return for such increments the practitioner should be required to attend at least one week's course of post graduate study in a year. With regard to pension, the Union asked for this on a scale comparable to the pensions offered in other branches of the public service. It suggested that the cost of pensions might be met by the allocation of something like 3s per year per head.

The Union's demands consisted of a basic capitation fee of 13s 6d, a further reserved fee of 4s 6d to be applied for pensions and three-year increments, the same consideration from the Minister of Health as was given to other health officers, and the appointment of a committee to consider the co-ordination of all health services. With regard to the question of juveniles, he said that it was well known that the 14-16 age period had a large accident incidence and many other troubles relating to adjustment to a new mode of living. If practitioners were to take the risk it was hardly likely that they would consent to accept a lower fee than was given for other classes, for example, 18-20, with no special risks.

The Position of the MPU

Mr Harrison (for the Ministry) asked whom the Medical Practitioners Union represented and how its interests differed from those of the Insurance Acts Committee. He was not sure whether he was fighting one opponent or two.

Dr Ward: You are fighting two. The MPU is a trade union. It appears here virtually on the same platform as the British Medical Association and a large number of our members are members also of the Association. But we do feel that the line of approach of the Association has been made on a narrow basis and is not the best. There is an honest difference of opinion between us without any real hostility.

Mr Harrison said that the Chairman had rather indicated that he regarded a good deal of the memorandum of the MPU as outside the terms of reference of the Court. He himself submitted that the whole of it was entirely out of the terms of reference and was certainly something that neither the Ministry nor the I.A.C. expected to be discussed. (Dr Dain assented.) If he had to deal with this he would be in a great difficulty.

Dr Dain said that the I.A.C. represented the whole body of insurance practitioners, who elected from their number the Panel Committees, which were statutory bodies under the Act. Groups of Panel Committees appointed representatives to the Insurance Acts Committee, and individual Panel Committees sent representatives to the Annual Conference which instructed the I.A.C. That position had been recognized for many years by the Ministry, and in any matter of business the I.A.C. and the Ministry dealt with it by negotiation when it concerned for example, alterations in the articles or terms of service and when as occasionally happened the capitation fee came up for consideration, memorandums were exchanged between the parties.

Dr Ward asked whether the terms of reference of the Court were before the constituent bodies who composed the Insurance Acts Committee.

Dr Dain said that the Insurance Acts Committee on that matter took full responsibility.

Lord Amulree from the chair said that this Inquiry was between the Ministries on the one hand and the representatives of the British Medical Association on the

other, and he took it that Dr Ward's position was that of a witness helping the Court to arrive at a proper decision.

Dr WARD: That is a matter for you to rule. We regard it as a public inquiry when everybody may be heard.

The CHAIRMAN: You are here among other people to assist the Court in enabling it to arrive at a proper decision. We have taken your evidence, and I do not see where your grievance lies.

Dr WARD: The two parties have prejudiced the Inquiry by exchanging memorandums over weeks past, and the Inquiry is conducted on a narrower basis than that announced by the Minister of Health in March of this year. We have been prejudiced in the case we might have been able to prepare. The Minister said clearly in March that the whole question would be put before the Court, but it is only a part of the case which is before the Court.

Case of the Ministry of Health and the Scottish Office

Mr T. D. HARRISON, in opening the case for the Ministry, said that he had with him certain officials who in due course would be tendered as witnesses. There was no point at issue in this case which raised any question with special reference to Scotland, and unless the Court wished to hear a special witness in regard to Scotland he did not propose to call one. Before proceeding to criticize the case put forward on behalf of the doctors there were two points on which it would be as well to make a few general remarks. The present Court was free from at least one of the complications which were present in 1924. There was on this occasion no sort of attack being made from any quarter on the medical service as a whole. The Minister of Health had never said that the service was other than a good and efficient service. Neither in 1920, when a similar point went to arbitration, nor in 1924 at the Court of Inquiry, was anything like that said on behalf of the Minister, but in 1924 there was quite a hot attack from other quarters on the way the system was being worked and it was argued that the service was not only unsatisfactory in many respects but unduly expensive. It was no part of the Minister's case in 1924 that the service was not satisfactory, and his predecessor Mr. (now Sir Maurice) Gwyer expressly dissociated himself from any attack of that kind. On this occasion no attack was made from any quarter. No doubt the service was not perfect, no service was or ever would be, and all doctors had not the same degree of skill, ability or even energy. But the Minister did not question in any way that the service was, within its limitations, a good and efficient service. To-day it was widely recognized that insurance practitioners were performing quietly and steadily a service of national importance and it was the earnest hope of the Minister that all parties engaged in this work might co-operate with the central department in improving and where possible extending the service to the lasting benefit not only of that large section of the population which came within the direct scope of medical benefit but of the nation as a whole.

No "Niggardly Economy"

The second point was that the Minister had not approached the question of the capitation fee either generally or by comparison with 1924 in any spirit of niggardly economy. The Minister had shown no desire at any stage in the history of the scheme to beat the doctors down or to secure some sort of service at the lowest possible rate. On the contrary, the constant aim of those associated with the central administration had been from the very beginning to secure the best practical service supplied by the largest number of best available doctors and to pay to those doctors a fee which would be a fair remuneration for the work they did and at the same time would have regard to the nature and extent of the service actually supplied by those doctors while not imposing

an unfair burden either, through his contributions, on the insured person or on the national exchequer. The Minister had shown in the present case a studied moderation in the way he had put forward the documents and although the factors which indicated that a reduction of the fee would be justifiable had been within his knowledge for some time it was not he who had taken the initiative in these proceedings. That was not the origin of the present Court. The origin was that the Minister had been asked by the doctors for an increase in the fee. It was evident that there was a section of the medical profession engaged in insurance practice which considered itself down-trodden, underpaid, and bullied by the Ministry. He hoped that was only a small section. Possibly it was a legacy from the earlier days of insurance. The old attitude of hostility had changed. Young men had come into the service who had never known the bitterness of the original disputes. If anything he said could remove remnants of suspicion that the Minister was there to "down" the doctors then he would not have wasted his time.

Mr Harrison went on to remind the Court of the past history of the capitation fee. When the service started in 1912 the fee provided for the doctors was based on such information as the Government possessed concerning the average payment in club and contract practice.

Dr Dain objected at this point that Mr Harrison was going back further than the period covered by the reference to the Court.

Mr Harrison said that he did not include Dr Dain among those who regarded the Minister with suspicion, although the tone of the rejoinder made by the Insurance Acts Committee had caused him to wonder a little. He did not know whether it was in the nature of the "retort courteous" or the "countercheck quarrelsome."

Admission of Juveniles

The first move which gave rise to the present proceedings was the announcement by the Minister of his intention to introduce legislation to extend national health insurance so far as medical benefit was concerned to juveniles (14-16) in insurable employment. The insurance of this class did not include sickness and disablement benefit and as those benefits carried with them certification it followed that the doctors would be released from the obligation of issuing certificates in the case of these persons. Before introducing legislation it was of course necessary to find out how much the new scheme would cost. Accordingly negotiations were entered into with the Insurance Acts Committee as to the proper fee, and the Minister suggested 6s. which was refused by the I.A.C. It was said that the Minister was attaching too much importance to the point that these juveniles would be relatively sickness free and thereupon he suggested a fee of 7s. 6d., but this also was declined. The I.A.C. not only said that there must be the full capitation fee for these juveniles but that a higher capitation fee all round was called for. That was the first time that that point was raised officially.

Dr Dain pointed out that in 1934 or 1935 the Committee had approached the former Minister of Health then Sir Hilton Young, on the subject of the increased capitation fee.

Mr Harrison said that that was not made as a formal demand. It was as a consequence of the recent history he had outlined that the matter came before the present Court. He was not suggesting that the Minister's counterclaim that the fee ought to be reduced to 8s. was a second thought on his part. All the information justifying that claim had been in his possession for some time past but it was not he who had raised the issue. The Court ought to know what the position was with regard to the cost of medical services and what the doctors' claim was in hard cash.

Dr Dain protested that this was outside the terms of reference of the Inquiry. The question of where the money should be found ought not to be introduced into the discussion.

Mr Harrison said that he was not even going to make any suggestion as to where the money should be found, but the Court must know what it was doing. As a matter of figures, when the one million juveniles came in there would be about 19½ million insured persons. With that number one shilling either way on the capitation fee meant about £955 000.

Dr Dain: I object to it being put to you as a reason which should influence your decision, the amount of money to be found.

Mr Harrison: I am not putting it as a reason, but only that the Court may know what it is doing.

Dr Dain: A very fine distinction, my lord.

Criticism of Committee's Records

Mr Harrison then turned to the examination of the Committee's case. The figures which had been adduced showing the number of services although valuable as a method of comparison, did not necessarily prove that the service given was a better or a worse one. One doctor might diagnose a case correctly at once, another doctor, not so clever or so fortunate might have to pay a number of visits before he diagnosed a case. Yet the first service must be the more efficient.

Dr Dain said that he did not follow that argument or agree with it.

Mr Harrison said that the figures were not in themselves a complete test of the nature of the service being rendered. Again it was a flat rate capitation fee which was being dealt with and they could work only on averages. When working on averages it was very important to make comparisons between averages of the same kind of things. It was necessary to be sure that the average was a true one not vitiated by any fault, and then care must be taken to compare like with like. It was not safe to compare figures compiled on one basis with figures compiled on another, still less to compare a figure compiled on a basis which was stated to be adequate and accurate with a figure which was stated by the same authority to be unreliable.

He was not impugning the care with which the figures had been collected or the spirit in which they were put forward but the comparison was made between the items of service per insured person per annum stated to the 1924 Court (3 75) and the items (5 0) on the figures now available as the average of the last seven years and Dr Dain had told the Court exactly how those figures were prepared. Having averaged out these records for the last seven years he compared the result with the figure, 3 75 for 1922 which the Court might be surprised to hear, was obtained from the official record cards and according to Dr Dain hopelessly understated the position. The other side said that the official records revealed a lower number of services than were actually given. On the other hand while the IAC figures for 1922 and for 1936 were obtained on a different basis so making comparisons impossible the methods adopted on both occasions by the Ministry were to all intents and purposes the same. Wherever the inaccuracy might be whether in the official records or in the Committee's method the two sets of figures produced an entirely different result. After pointing out some discrepancies between the figures Mr Harrison argued that the Committee's averages were quite unreliable because they had not been obtained in a manner which fulfilled the canons of statistical science.

Adequate Sampling

What were the essentials for a proper sample? (1) The sample must be selected absolutely at random. (2) there

must be no possibility of bias in the selection of the sample, either deliberate (of which he did not accuse the other side) or introduced automatically by the nature of the method adopted, (3) the sample must be sufficiently large, for the larger the sample in relation to the class investigated the smaller would be the margin of error. In the case under consideration the doctors were spread all over the country, working in all sorts of districts and in all sorts of conditions as to population. In dealing with such a class three further essentials must be laid down: (1) the method must be such as to secure that all parts of the country were represented in the sample with sufficient uniformity, (2) all types of practice should be included in their proper proportions, (3) care must be taken that the sample did not consist only of people having a high average or a low average—there must be a proper mixture of doctors with high, medium, and low numbers.

How did the figures brought forward by the Committee comply with these requirements? Mr Harrison proceeded to read an extract from an article by Dr A. Bradford Hill in the *Lancet* of January 9, 1937, Dr Bradford Hill was medical statistician to the Medical Research Council, and he wrote as follows:

A sample which is composed of volunteers or self selected individuals is not likely to be a random sample of the universe from which it is drawn. If for example a treatment of colds by vaccine is offered to a group of persons the volunteers are likely to belong mainly to that section of the group which suffers most severely from colds and hopes for some advantages from the treatment. They are in that event a select group not comparable with the remainder of the population from which they were drawn. In such cases the question must always arise: Is the act of volunteering correlated with any factor which may have an influence upon the final results of the experiment?

In the case of the Committee's figures the doctors who made the returns selected themselves. He supposed that a certain number would start sending in returns and then drop out. But that was the way by which were obtained the individuals on whose records the sampling system was based. They were volunteers who knew why they were asked to volunteer. There were two types of person who would be more likely than others to agree to keep these records and go on keeping them and those were just the people who would produce, if the sample were confined largely to them a higher figure than the true average. The first was the practitioner who was exceptionally enthusiastic about insurance practice and who was in fact giving a larger number of services than the average man. He was the type of doctor who would go out and see a patient that same day, whereas another would put it off until the day after to-morrow. He felt sure that there were a number of doctors who did give a much higher average of services than the common level. They were just the type of people who would fill up the returns, and he did not suppose that even they were enthusiastic about insurance practice as they were would be unaffected by the knowledge that any high records of theirs would be very useful to those who were asking for the returns. The second class of practitioner was one who knew that he was giving a higher number of services than the average owing to the conditions of his practice and was possibly smarting under a certain feeling of grievance that he was not getting adequately paid. He would be likely to return cards showing a maximum service. On the other hand there was no temptation for the doctor who knew that he had a low average to make such returns and he would remind the Court of what Dr (now Sir Henry) Brackenbury said at the previous inquiry. I know from experience that a doctor always has the impression that he has done far more and has seen a greater number of patients than he really has. If he totals up the number of people he has seen he is surprised to learn how few they are. He did not think that that conflicted with the general experience. Altogether

there was no security that in this sample not only high but medium and low records were introduced. The tendency was for the high to come in and the low to remain out.

Ministry's Method of Ascertainment

Turning to the method of ascertainment adopted by the Ministry Mr Harrison said that the doctors were selected on two grounds only—that they must have more than 500 persons on their lists, and that they were known from the personal experience of regional medical officers to be careful record keepers. The sample was well spread over the country. Urban, mixed, and rural practices were selected approximately in the proportion 7, 2, 1, being roughly in correspondence with the number of insurance practitioners engaged in these types of practice. From each selected practice 500 cards were taken, perfectly at random, as set out in the appendix to the Ministry's case (*Supplement* May 29, p 324). The advice of Mr Kyd, principal actuary in the Government Actuaries Department, had been taken on the rightness of the sampling.

Mr HOWORTH. Granted that the cards are properly filled up by the doctors.

Mr Harrison said that the same thing applied to 1924. There was no reason to suppose that the proportion of bad record keeping differed as between the two years. There were doctors who were known to be poor record keepers, but the record keeping on the whole was really well done, and if there were any doubt on that score he would say again that the records were selected from doctors who were known by experience to be good record keepers.

In 1924, in connexion with the Royal Commission of the following year, a test sample was taken on exactly the same method as was employed in 1936, and the figures were set out in paragraph 15 of the Ministry's case. In its rejoinder the Insurance Acts Committee stated that its own figures covered a great many more insured persons—namely, 1½ millions—the Ministry's figures covering only one third of a million. That was plausible, but misleading, because, of course, the Committee got its total of 1½ millions by taking all the insured persons on their doctors lists whereas the Ministry had based its figures on the method of taking a sample of 500 cards from each practice. In point of fact the actual number of insured persons who were on the lists of the doctors whose cards were inspected was just over one million. The cards examined were those which were in the doctor's possession at the close of the year and any persons who had not been on the doctor's list during the whole year were eliminated. He described the adjustments and corrections made in the figures as set out in the memorandum. The result of the survey was that the average number of services per card examined was 3.66. A special investigation of services given to persons who died during 1936 was made, and showed that these persons received 9.17 services. In addition the particulars of services given in 1936 to persons who died after the end of that year but before the date when the investigation was made were taken out. The period between the end of 1936 and the date of the investigation was about one-fifth of a year and on the assumption of a death rate of 10 per thousand a little calculation showed that the inclusion of the records in respect of attendances on persons who had died increased the average number of services per insured person during 1936 from 3.66 to 3.72.

After corrections and the weighting described in paragraph 18 of the Ministry's memorandum the total services came out at 4.12 for 1937 as compared with 3.99 for 1924, an estimated net increase of work of about 3½ per cent. The appropriate increase in the capitation fee on this account was about 4d., which might be taken as a set-off to the additional cost of living.

To show how carefully the survey was made an examination took place of the shift of population since 1924. In the North of England and South Wales there were at both periods more insurance practitioners per insured population than the average for the whole country. In proportion to the insured population the number of records examined in these two areas was about 9.4 per cent. higher than the number examined for the rest of England and Wales in 1924 and about 16.5 per cent. higher in 1936.

Prescriptions as a Criterion

He next took up the point which had been made that according to the Ministry's returns there had been more prescriptions issued to patients in 1935 than there had been services. He had a complete answer to that argument. The suggestion seemed to be that there was some relationship between the number of prescriptions and the number of services. He contended that the number of prescriptions was not an accurate guide to the totals in the number of services. If there were any necessary connexion between the number of prescriptions and the number of services it would be shown in Scotland also, but he had the figures of the number of forms as they called them in Scotland, a form containing one to three prescriptions, and in 1924 the number of forms per person in Scotland was 1.7, and had fallen ever since, the figure for 1924 being the highest on the list.

Dr Dain said that the records in Scotland were on a different basis, and to compare the figures of Scottish practice with English figures might mislead the Court.

Mr Harrison said that the same argument applied to England. Frequently more than one prescription was entered on one piece of paper. Special examinations were made in 1920 and 1930 to ascertain the number of prescriptions per script in England and Wales, and in the former year the average was 1.15 and in the latter year 1.276. A special check had just been made in three of the large pricing bureaux—namely, those of the north-eastern district, Lancashire, and the south-eastern district—and it was found that the number of prescriptions per script had gone up. If one assumed that what had happened in those districts operated throughout the country it would appear that the average number of prescriptions per script had gone up to 1.34. Sometimes doctors wrote on two pieces of paper, which counted as two prescriptions but there was only one attendance. What the figures showed was that of 100 patients who received service something like ninety-two got a prescription on their attendance or visit and the remaining eight did not. He thought that was a reasonable percentage of people who did not get prescriptions. The figures were only in respect of persons who were entitled to prescriptions; no correction required to be made in respect of doctors who dispensed.

Practice Expenses

Coming to some general considerations, Mr Harrison said that he could not agree that, as suggested in the I.A.C. case the practitioner incurred a heavier responsibility when he sent his patient for examination to his hospital. Nor did he see the relevance of the argument based on the ageing of the population. With regard to practice expenses everything that he had said about the principles which should be followed in taking a sample applied here. These samples again were taken entirely from volunteers and without any attempt to sort them out. The practices with lists of 2,000 or 3,000 were large practices and the ratio of expenditure did not compare with that of medium practices. He examined the figures given in the Committee's case in some detail and said that he found difficulty in understanding how a practitioner could possibly spend on his practice the sums indicated—namely, on a practice with a gross return of £1,500 practice expenses to the amount of £500. Pro-

fessor Bowley had given the budget of an average doctor's family from which it appeared that the amount of rent and rates chargeable to the practice—namely, one third of the total—was £41 and fuel and light £18.

Dr Dain raised the objection that Professor Bowley's figures ought not to be taken unless Professor Bowley was present, he had been present on the previous day, and Mr Harrison had intimated that he did not wish to ask him any questions.

Mr Harrison said his only point was that when all the deductions for practice expenses were taken as implied in Professor Bowley's table quite a large sum—roughly £300—had still to be accounted for. What was that £300 spent on? He supposed it included bringing in a locum-tenent for the summer holiday, but that would not be more than 20 guineas. He agreed that if an assistant were employed this would be a substantial item, but he had figures which seemed to show that the number of assistants for insurance doctors was very small. Again, an assistant was not ordinarily required solely for insurance work. Unless a doctor had a list of 2,500 or over the only reason why he employed an assistant was that he and the assistant between them could run both the insurance and the private side of the practice. The assistant was brought in not because he was necessary for insurance work but because the doctor in addition to his insurance income might derive a large income from private practice. In those circumstances salaries of assistants ought to be eliminated from the computation just as the cost of drugs and charges for bad debts ought to be eliminated as having no relation at all to the ordinary insurance practitioner.

Lord Amulree said that he wished Mr Harrison would clear up the point about assistants. Why should not the assistant's salary be included in the reckoning as practice expenses whether the list was over or under 2,500?

Mr Harrison thought there was something to be said for disregarding the salary of assistants all the time but when the practitioner was compelled by the regulations to have an assistant owing to the size of his list it was very difficult to say that the salary should not be taken into consideration. A man who wanted to enlarge his business and found he could not do it single handed took in someone else, and his income was thereby increased. But there was this difference in the case of the practitioner with a list of 2,500 that he was not free in the matter. Therefore it would be fair to include the cost of an assistant when the list was above that level.

Lord Amulree asked what was the difference between an assistant and a locum-tenent. Was it merely that one was permanent and the other temporary? Mr Harrison explained that the former actually took the place of the doctor when the latter was away.

Lord Amulree. In other words holidays with pay.

Mr Harrison said that was really what it amounted to. The doctor's income from his insurance practice was continuing during his holiday and the cost of the locum-tenent being reckoned among practice expenses for the determination of the capitation fee he was really having holidays with pay.

The Position of Juveniles

Finally Mr Harrison dealt with the question of juvenile entrants. The fact that the Ministry had offered 7s 6d for these persons did not mean that that was thought to be an accurate amount and at the time it was suggested the Ministry had not got the result of the special survey referred to in paragraphs 22 and 24 of its case which showed a substantially decreased number of services for people of these ages. The Ministry thought that doctors should get something between one third and one half of the capitation fee in respect of juveniles. If this was to be regarded as a rate for the whole of the insured population it meant a reduction of 2d or 3d.

Dr DAIN. Is it assumed that the whole million juveniles will go immediately into employment?

Mr HARRISON. It is assumed that only two-thirds of the people of that age will get employment.

Dr DAIN. That makes it only some 700,000.

Mr HARRISON. No the million represents the two-thirds.

Dr DAIN. The absolute number of the persons from 14½ to 16 at the moment is one and a quarter millions and it will go down and there are no means by which it could be increased.

Mr Harrison having concluded his address for the Ministry, Dr Dain suggested that the case put forward by the Ministry so far as concerned the amount of work done by practitioners was extremely meagre. Was it really the best evidence that the other side could put forward? Mr Harrison replied that five counts had been taken—in 1922, 1924, 1930, 1934, and 1936—and the expert advisers of the Ministry had assured them that the method adopted was a very good one for arriving at the correct figure.

Third Day

Motoring Costs

The Court sat only in the morning of May 28, when technical evidence was taken.

Mr W. C. BURNS, deputy to Captain A. Hudson, chief transport officer in the Engineering Department of the G.P.O., gave evidence in support of the figures put forward by the Ministry with regard to motoring costs. The first figures were the Treasury rates allowed to civil servants for cars used on official business. These figures for 1924 were a contemporary document, arrived at after full discussion between experts on behalf of the Post Office and the Whitley Council and with a full knowledge of the conditions of motoring at that time. The same thing applied to the revised rates fixed in 1933 and reviewed in 1937. Not merely had the conditions of motoring changed as between 1924 and 1937, but the very cars themselves had changed out of recognition. If a car of 1924 appeared on the streets to-day it would be an utter anachronism. Thus there was the danger of comparing unlike things. Luckily the Ministry had not to rely on the authority of one or two individuals, as the doctors did, but they had the authority of the representative body of the motoring industry, the Society of Motor Manufacturers and Traders. When dealing with the question of motoring for a very large class of persons, and having in mind the fact that cars had radically changed their character there was only one method of arriving at a reliable figure—namely to take a cross-section right through the range of cars of different h.p. to find some feature making it possible to compare the car of 1924 and that of 1937. The feature selected was the price per h.p. of the chassis. Having taken the average h.p. price of ten selected groups of cars they had gone on to find out what was the proportion of h.p. sold in these various groups in the two years and by that means arrived at a composite figure which was an expression of the average price per h.p. of a complete range of cars.

Roughly twice as much was paid for a car of equivalent h.p. in 1924 as would be paid in 1937. Motor travelling costs since 1924 had come down by nearly one half and it was a fair assumption that the change applied to the cars used by the medical profession in the same way as it did to the cars used by the general motoring public. He was proceeding to examine the figures given in the Ministry's case when Mr Robertson, a member of the tribunal, expressed some scepticism with regard to the method adopted. He pointed out that taking a range of cars of ten different horse powers the range would be different in the two years 1924 and 1937 and in the latter year it would include a much larger number of small cars. He thought one ought not to

assume that the price of the high h p car had fallen by 50 per cent

Depreciation of Cars

The witness said that as the 1924 car was so very different from the car of 1937 there was no proper basis of comparison between any two particular cars, and therefore it was necessary to take a general average over the whole range of cars. It was said that 10 h p cars were not used by doctors, but the Ministry, in putting forward those figures, had assumed that the sales of cars which applied to the public generally applied also to insurance practitioners. As to a fair depreciation, it had been suggested that at the end of the first year a car had depreciated approximately to 55 per cent of its sale value, at the end of the second year to 50 per cent—that is to say, a car was worth only half its original value after two years—and to 40 per cent after three years. If a doctor bought a car for £250 and sold it after two years he would lose per annum on depreciation £62 10s, if he sold the car after three years his loss would be £50 per annum. He took exception to the figure given for depreciation in the I.A.C. rejoinder—namely, £75 10s per annum—and he argued that on the basis of the other figures given this amount of depreciation would mean that the average insurance practitioner sold his car and got a new one every twelve or eighteen months. In his view one could get 40 per cent of the original value of a car after three years' use, but if the average practitioner put aside £75 10s for his car yearly on account of depreciation it must be assumed that at the end of three and a half years a car purchased for £255 would have no sale value at all, whereas it should have a sale value of £100. The other side had no right to assume that a doctor was going to sell his car annually at a loss of something like £112 on a car costing £250, nor was it right to assume that any considerable number of practitioners would sell their cars within two years, because so far as repairs were concerned these during the first and second years were practically negligible. He thought it reasonable to assume that the fair period to take for the life of a car used by a doctor was not less than three years.

He also criticized the figures given by the Committee's expert for tyre cost. The Ministry had taken 15,000 miles as a very conservative estimate of the life of a modern tyre. He had been interested in Mr Scott Hall's statement with regard to maintenance, and he noticed that his costs provided for the vehicle to be thoroughly washed and polished three times in two weeks. He thought that with three washes a fortnight the doctors were "doing themselves well".

Mr HOWORTH a member of the Tribunal. Do you suggest that doctors should wash their own cars?

Mr BURNS. No Sir but at doctors premises one very frequently finds maids knocking the dust off the car.

The witness also criticized the figures given for 1924 costs as being too low. He had been unable to obtain from the expert who had spoken for the Committee a clear statement as to what was the life of a car in 1924.

There was some disagreement between the witness and Mr Scott Hall as to the cost of an Austin Twelve in 1924. The witness cited one compilation to show that it was £450, Mr Scott Hall suggested that it was £100 less.

Operating Costs

Mr BURNS further said that he considered the basis upon which the schedule of operating costs given in the Committee's rejoinder was constructed to be not sufficiently representative of the actual conditions of motoring among the medical profession. To assume that a doctor would change his car in less than every three years meant that he was not motoring in a reasonable fashion nor exercising prudence in conducting his motoring at

an economical cost, and that he was a devotee of changing fashions, for which the public should not be called upon to pay.

Dr DAIN protested that this was an expert witness on the cost of motoring and it was out of place for him to go into the ethics of motoring expenditure. The Committee's view was that the reduction in motoring costs was much less than the Ministry supposed. He elicited from the witness that he had no personal experience of the type of car used by doctors nor of how such a car compared with the car used by a civil servant on official duties. Dr DAIN pointed out that the doctor's car stopped and started a very great number of times to the mile, much more so than cars used by other sections of the public. The witness said that he could only take probabilities as disclosed by the use of cars by the general public.

We are not talking about the general public. We are concerned with the use of cars by doctors. You would not suggest that the class of doctors has changed in status or work or use of cars during this period of thirteen years?—I have no knowledge of any change of status.

Do you still consider five years a proper life of a doctor's car?—I do not know from my own knowledge what the life of a doctor's car may be.

If you were told that in fact doctors kept their cars for three years, the proper figure for cost of car in the Ministry's table would be £51, not £28 16s.—That latter figure assumes five years' life of a car.

Do you seriously suggest that a doctor can buy a car of the same type for 50 per cent. less than in 1924?—The trouble is that cars have so changed between 1924 and 1937 that you cannot get out a comparison at all. The 1924 car has very little relation to the 1937 car, and therefore you have to take the average over a large range.

Would you agree that the rate of depreciation of a 1937 car is greater than on a 1924 car?—Very slightly.

Mr Scott Hall, who was recalled, said that in his experience a small minority of doctors sold their cars at the end of one year, a considerable number at the end of two years, a somewhat smaller number at the end of three years, and a minority over three years. He also pointed out that the more expensive cars depreciated on the market more rapidly than the cheaper ones.

Actuarial Evidence

Mr J G KYD secretary of the Government Actuary's Department, gave evidence on the number of services given by the doctors. He said that he was not consulted by the Ministry of Health before it took out this sample but afterwards the Ministry did consult his department and it fell to his lot to examine the methods adopted by the Ministry in so doing. In his view the sample taken was of sufficient size to render the results deduced therefrom dependable, it was also of sufficient spread throughout the country in relation to the various factors that might affect the result of the sample. Information was obtained from each of the thirty three regions into which England and Wales was divided and from each region he understood twenty doctors were taken. The selection of these doctors was not left to the doctors themselves. The choice was made by the divisional medical officers and this had the result of spreading the sample adequately as between urban rural and mixed practices. It was very difficult to be quite sure that the result of a sample in any field of observation would give a satisfactory result but if the data were in any way biased the result was hardly worth publishing and he had felt it his duty to point out where there was in fact any bias in this sample. In view of the fact that the doctors chosen were definitely known to be good record keepers any bias would be likely to show itself in the direction of increasing the number of services. He had satisfied himself that there was no bias whatever in the other direction.

Fairness in Sampling

Lord Amulree asked whether the witness considered that the number of cards examined was a fair proportion in considering a case of this kind

Mr Kyd replied that judging by ordinary statistical methods the number of cards was ample. The deviation or probable error which might arise was absolutely insignificant in a sample consisting of one third of a million persons where the variable which was being examined was so harmonized as the number of services given by a doctor to a patient. On a sample of 330 000 the probable deviation from the mean was so small as not to matter. He referred for illustration to the statement put in on behalf of the Committee. The main statement related to one and a half million insured persons but a new statement had been put in relating to about 361 000 persons, and on comparing the results of the two computations he found that the results of the smaller sample exactly conformed to those worked out in the case of the larger. He merely mentioned that as a proof that, although the Ministry's sample was limited to one third of a million persons there was no likelihood that if the sample had been much larger the results would have been different. The proportion which the sample bore to the universe from which it was drawn was slightly greater in the 1936 sample than in that of 1924. But equally with regard to the 1924 sample there was no bias against the case of the doctor.

Mr Robertson pointed out that one of the respects in which the Ministry's count was said to be superior was in trying to take account of different types of practice whereas the I.A.C.'s count did not make that differentiation. What importance would the actuary attach to that? In the case of a bigger sample such as the Committee had brought forward was any importance to be attached to differentiation of this kind?

Mr Kyd replied that the Ministry had analysed the average number of services in various types of practice, and he was rather surprised to find how little difference there was between the average number of services given in urban in rural and in mixed practices and also how little difference there was as between practices of various sizes. The following were the number of services given in practices of five groups of sizes

500-750	3.6 services
750-1 000	3.6
1 000-1 500	3.6
1 500-2 000	3.9
Over 2 000	3.5

He also examined the figures for different types of practice with the following results

Urban	3.68 services
Mixed	3.70
Rural	3.41

Mr Robertson asked whether in theory the sample was so large that the distinction between types and sizes of practice ought not to matter.

Mr Kyd agreed that if the sample was sufficiently large and distributed over the country there would be no bias on account of different types and sizes of practice. Mr Harrison pointed out that the bias in the case of the I.A.C. sample arose not in this respect but on account of its selection bias.

Bias in Selection

Mr Kyd said that it had appeared to him as an actuary that there was a great probability of a certain bias in the selection of cases in the Committee's return. He said he did not see how he could select a doctor to give information which he knew would be used in a case which might benefit himself. He was not a doctor, but he was put down as a record of a case. He said the point was that the figures for the

two years 1936 and 1922, had been arrived at on the same basis.

Mr Robertson said that the percentage of insured persons treated had grown markedly as between 1924 and 1937, but not to a greater extent than the number of services. It suggested to him that the number of services per insured person had gone down.

Mr Kyd replied that possibly from a purely actuarial point of view he might be able to give a reason for that. In the Government Actuary's Department they investigated the rates of sickness. The rates of sickness were made up of two factors: the number of persons becoming sick and the duration of the sickness, and in recent years it had been found that a considerable change had taken place in the composition of the rate of sickness. A larger proportion of people were sick, but they were sick for shorter periods.

Dr Dain took up the criticism that the Committee's sample was a random one. A selection at random was a selection taken haphazard or by chance but a selection made from a limited field of doctors engaged in a particular type of practice, and again limited to those who were known to be good record keepers, could not in any sense of the word be a random selection.

Mr Kyd said that he was inclined to agree with Dr Dain. But there was probably a slight bias in favour of the doctors by reason of the fact that doctors selected for this purpose were good record keepers. The bias showed itself in an increase in the number of services recorded.

You think that the limitation to practices of a certain size does not vitiate the count?—The run of figures from 500 to 2 000 is so uniform that I cannot believe that the exclusion of practices with fewer than 500 persons on the list would vitiate the figures.

In a practice of 500 all the cards are counted. In a practice of 1 000 half the cards are counted, and in a practice of 2 000 one quarter. Is that likely to have any effect on the result?—So long as the cards are selected at random I do not think that statistically this makes any difference unless of course the people whose names begin with A or with B are more prone to illness than others.

The Chairman announced that the Court would, if necessary sit the whole of the following day to complete the evidence.

Fourth Day

Evidence of Ministry's Medical Staff

At the resumption of the hearing on May 29 Dr R. PATTERSON, senior medical officer of the Ministry of Health, gave evidence. He said that he was for a number of years an insurance practitioner afterwards spending nine years as regional medical officer and during the last eight years he had been concerned with the supervision of the regional medical staff among other matters. Being a professional man he did not want to give the Court or anyone else the impression that he was attempting to say anything derogatory of the medical profession anything he had to say was derogatory only of their excessive claims in certain directions.

It was claimed in the case put forward by the I.A.C. that the profession had an increasing responsibility for the prevention of disease. It was true that the whole future of the medical services in this country was subject to change and sooner or later there must be a linking up of all services in which the general practitioner would continue to play an important part. But the Court was asked to consider what the general practitioner did to-day for his patients and not what he might do under a co-ordinated public health service. Generally speaking, normal healthy persons did not visit the doctor and that

observation applied particularly to juveniles. It was claimed, and no one denied that the science of medicine was advancing rapidly, but here again, how far did these advances affect the work of the general practitioner? The case presented by the Committee mentioned ulceration of the stomach and duodenum. One of the saddest recollections of an old practitioner was the great amount of work thrown upon him by what was known then as chronic dyspepsia or gastritis. To-day the condition of these people was diagnosed quickly and they were operated on or treated medically and in the majority of cases made good recoveries. Modern advances, so far from adding to the practitioner's responsibility, had relieved him of much of it. He instanced the treatment of varicose veins. These persistent conditions gave great trouble in the old days, but modern treatment enabled the patient to be well and about within a short period. The practitioner here had been spared much distasteful and laborious work.

It was claimed that increased time was spent over the examination of patients, and he was astonished to notice the sphygmomanometer mentioned for that instrument was in use by careful doctors a quarter of a century ago. As for sera and vaccines, in 1935 there were dispensed by insurance chemists 25,760 prescriptions for these. He agreed that this did not tell the whole story, for an insurance doctor might purchase the material himself and claim repayment, but in the majority of cases this was not done, and the figures suggested, when compared with the total of the insured population, that the incidence of cases held to require this treatment in a particular practice was negligible. With regard to psychological treatment, also mentioned, a certain amount of psychotherapy had always entered into the work of the doctor, the "good bedside manner" was nothing else. But skilled psychiatric treatment was a matter for the specialist.

Medical Records

On the value of medical records, Dr Dain and he parted company. The contemptuous dismissal of medical records, ticks and so on in the I.A.C. case must have left an impression that doctors were having forced upon them some most disagreeable task. But these medical records were the result of the recommendations of a very important committee set up by the Ministry, with Sir Humphry Rolleston as its chairman, and numbering Sir Henry Brackenbury and Dr Dain among its members. The chief purpose of the record was to help the practitioner in the treatment of his patient. Dr Dain had claimed that even the most complete and careful clinical recorder did not take these cards out on every occasion he saw a patient. Then what was the record for? Any conscientious doctor would almost refuse to see a patient unless he had the notes of the case on the table before him. To say that doctors as a whole were not using records in that way was simply not true. When he was regional medical officer he found that the best records in every sense were kept by the men who made a rule of having the record out on every occasion of seeing a patient. He agreed that there were those among the profession who always objected to taking records. He had never understood that agitation. The Ministry had always claimed that the primary purpose of the record was a clinical one.

After clearing up a slight misapprehension with regard to the statistics of prescriptions Dr Paterson claimed that there was very little connexion between the amount of prescribing and the number of services. He pointed to what was happening in Lancashire. Why Manchester and Salford required apparently so much more drugging than Rochdale he could not say, but while the prescriptions in Manchester and Salford were about seven per insured person and those in Rochdale about four the number of attendances in both areas was about the same.

It was said that more people were coming to see the doctor. But for two reasons the Ministry believed that the doctor was not called upon to give more services. On the one hand more serious illness was treated in hospital,

and on the other more people were seeing the doctor for trivial illnesses, not necessitating more than one or two attendances. Therefore it was quite understandable that while the proportion of persons seen had risen considerably, the amount of work required of the doctors had not increased in anything like the same proportion.

With regard to juveniles he maintained that the number of attendances required must be very much less than that required for adults. He found it difficult to suppose that healthy boys and girls of 15 and 16 would on their own initiative go to the doctor for advice on health. It was agreed that mortality rates were not a good guide to morbidity rates, but it seemed evident that it must be the older people approaching the ages in which the death rate was highest who gave the doctor more work. He had tried to discover what were the complaints at the age 15-16 which, while not incapacitating the person for work, would require attendance from the doctor. These people were, generally speaking, beyond the age for infectious diseases, and they had not reached the age when more serious chronic ailments generally began.

A question being raised on the number of juveniles who would come in, Mr Kyd, actuary on the Ministry's side, said that the number of children of ages 14-16 who emerged this year was about one and a half millions. By 1948 it was estimated that it would have fallen to 1,200,000.

Dr Dain pointed out that very many of these children did not leave school until they were 14½, and the lag in many cases between leaving school and entering employment would further reduce the figures.

Mr Howorth, a member of the tribunal said that he had made some calculations based on prescription totals from which it appeared that there had been an increase in the number of 29 per cent between 1924 and 1935, from 34,624,000 to 44,650,000. During that same period the number of insured persons entitled to prescriptions had increased by 17.2 per cent. Allowing for that increase in the number of persons, it looked as if there had been a real increase of work, as indicated by prescriptions.

Dr Paterson replied that it was common ground that there was a very considerable amount of unnecessary prescribing, but he pointed out that in some parts of the country, notably Scotland despite the claim of increased services, there had actually been a fall in prescription frequency during these years.

Dr Paterson Cross-examined

Dr Dain put certain questions to Dr Paterson.

What is a good record keeper?—A man who takes his record out for every patient notes the fact of his attendance on the patient and makes a suitable clinical entry.

How do you know who the good record keepers are?—The regional medical officer is charged with the duty of routine inspection of the records of doctors.

How do they know that the doctors whose cards they are inspecting have taken the card out every time and made a tick on every occasion?—It is difficult to explain but I am prepared to examine any set of cards and say at once whether a man has done it in that way. There is a difference in appearance between a record made in that way and a record written up afterwards.

Is it claimed that the good record keepers are 100 per cent accurate?—No, but I could run my eye over hundreds of men whose records come mighty near 100 per cent.

If 100 per cent is not claimed what percentage of accuracy is claimed?—That is a question practically impossible to answer. To say whether a man was 100, 99 or 98 per cent accurate one would have to sit with him day by day and see him working. We have no standard of accuracy in meticulous detail.

You cannot get past 100 per cent accuracy?—Oh yes you can. We know of one man who got 200 per cent accuracy by the simple expedient of including every visit as an attendance at 0.

Can you give us an assurance that the error in recording is not more than 5 per cent in the practices you have taken?—I can give you no guarantee at all

When you were in practice were you a 100 per cent recorder?—I should say I was. I had a paid secretary to assist in the work

Would you agree that there are likely even in the most careful practices to be omissions?—Surely

I put it to you that in practice there would be such a number of omissions that 100 per cent would almost certainly not be obtained?—I said there was a risk of it not being obtained

Would you maintain that the count is more accurate to-day than in 1922?—I think on the whole yes. I would not press it very far

Are there not a large proportion of very large practices in the Ministry's computation?—Well there are none with fewer than 500 names

In fact it is the large practices that have been examined if 1,500 is the average. Would you not expect a larger error in recording in a larger practice?—I have always claimed the opposite

How many of these practices were partnerships and how many of the practitioners had assistants?—The 658 practices consisted of 824 practitioners not counting assistants

Would you not think it likely that there would be a greater error in recording in a practice in which two people were engaged?—That may be. There is some possibility of falling between two stools

Would you suggest that there is no possibility of bias in the regional medical officer in favour of selecting men whose records he knows are easy to count?—I could hardly admit that

Your figures show 52 per cent of insured persons treated during the year. Your figures show 60 per cent. The method in both cases was to count the cards with ticks on them. Is not that evidence that our men are better record keepers than yours?—I cannot agree. From what I know of many of your men who keep the records I should not admit that

Do you know who they are?—One or two. I will not mention names but I know the methods they admit having adopted. In one case the dispenser in another room merely counted the heads of people who came on insurance business during the day

Do you think there is any doctor on your list or ours who takes his card and puts a tick on it when he has not actually given the service?—I agree that the doctor himself would not put a tick when he had not himself seen the patient

You agree that if the first year of the comparison had been a year of low sickness and the last year one of high sickness it would have been good for us?—Oh yes

Are your methods of computing still the same as in 1922?—So far as counting is concerned quite the same

If you had found a source of error in your method as used in the first period you would have corrected it and then you would have had to have come before the Court with figures which were not comparable?—Yes

If we had found a better method than was used in 1922 should we not be right in using it?—Surely

Could you give us any idea of the frequency of prescription in relation to attendances and visits?—In the type of practice I used to follow I should say the margin was 10 per cent in the practice

And that 10 per cent would include all cases you visited to see a doctor and the patients who came even other days for a consultation?—Yes. You would not get a smaller margin than 10 per cent. I don't think so

Is it fair to say that the method of computing services by a regional medical officer is the best method of computing services by a regional medical officer?—I don't agree

medicine had added to or taken from the work of the insurance practitioner. Until 1934 he had a large mixed practice in the West of England, with a list of about 1,800 insured persons, which formed about one-third of his total practice. It was only in difficult and obscure cases that he had found it necessary to send patients to hospital for advanced methods of diagnosis. There were very few general practitioners who had the skill or apparatus to use these advanced methods and even if they had, unless they were doing the investigations regularly, the opinions they formed were not to his mind likely to be accurate

It was his experience that it happened very seldom that healthy people came to him and asked him how to keep well. During his twenty-four years in practice he could only remember three such cases. The Insurance Acts Committee stated that there had been an improvement in methods of diagnosis in cases but he maintained that these methods were mainly confined to the domain of the specialist and did not concern the general practitioner or add to his work. Pernicious anaemia had been mentioned. The number of cases of pernicious anaemia any doctor was called upon to deal with were very few. In twenty-four years he could remember having to deal with only six cases. The practitioner was helped by modern methods, for he immediately sent the patient to hospital for specialist diagnosis and the specialist advised the doctor how to treat the patient. The supervision of the case was often taken out of the hands of the general practitioner, for the practitioner had to send the patient back for a blood count. Apart from writing a prescription for a liver preparation or giving an injection the practitioner had little to do with the treatment of such cases as pernicious anaemia

The question of gastric ulcer had been raised. By using x rays the diagnosis could now be established and efficient treatment started at a much earlier date than formerly, and owing to the improved technique of the operation patients operated on in recent years had fewer sequelae. With regard to cases of neurosis in his practice the peak of such cases was just after the war, and it never appeared to him in later years that there had been any serious increase. The treatment of serious cases of neurosis was a matter for the specialist. In his experience vaccines were not used as frequently now as in 1924. The results obtained had not been up to expectation and by the end of his practice he had given up the use of vaccines. If they were used, however, they meant that the patient got better more quickly and to that extent the doctors had less work to do. Ante natal examination was seldom called for from the general practitioner, the women usually calling in a midwife or attending the ante natal clinic. In recent years the district nurses were better trained than formerly and doctors handed over very much more work to nurses—the dressing of wounds and the like—than they did ten or twelve years ago. Work in respect of old age pensioners had also greatly lessened

Cross-examination

Dr. Dain said that this witness had given such an extraordinary account of conditions in general practice that he proposed to counter many of his statements by calling a fresh witness on his own side. He put a few questions to Dr. Mackenna

Do you agree that the general practitioner is required to know what the new methods are?—Certainly

With regard to pernicious anaemia would it be true to say that such a case which is not diagnosed ends rather early in death?—Yes

With regard to gastric ulcer do you adhere to your statement that x rays will give you a diagnosis every time?—No. I did not say that. We know that modern methods are not always infallible

Would you agree that the number of cases submitted to operation to-day is very much smaller than ten years ago?—I could not tell you

Is not the sphygmomanometer more used to-day in general practice and over a larger range of cases than 12 or 15 years ago?—I cannot tell you

Suburban Practice

Dr F J HARVEY also a deputy regional medical officer, gave further evidence supporting the Ministry's case. He said that from 1920 to 1935 he was a practitioner with a mixed suburban type of practice. It was his experience, notwithstanding what was said in the IAC memorandum, that the science of pathology and morbid anatomy still formed the basis on which the average general practitioner based his reasoning and his diagnosis, leaving the more intricate and detailed investigations in the hands of those in charge of hospital departments which were so well equipped to deal with them. While it was still the primary duty of the family doctor to arrive at a diagnosis and advise as to the treatment of disease it was in the main the prerogative of the public health service to deal with its prevention and the adaptation of the individual to his environment. The occasions on which a healthy insured person came to consult him on the subject of how to keep fit were so few that the time entailed was negligible. It was his experience that there was an increased tendency on the part of the insured person to consult his doctor for minor departures from the normal but this was probably offset by the increasing tendency of those in towns to go into hospital for the treatment of the more serious forms of disease and to consult the specialists in the out-patient department when they were suffering from ailments or from diseases requiring special investigation or treatment. The general practitioner was thus relieved of many of the more serious cases and of much anxiety and responsibility in general.

With regard to the improvement in the treatment of catarrhal conditions, he thought again that to a great extent the treatment was in the hands of the hospital or the specialist. Most cases of serious illness such as pneumonia and rheumatic fever were treated in the acute stage in hospital, and the more serious and complicated cases of fracture were also sent into the wards. It was always his privilege to exercise to the full his opportunities to advise in the early stages of disease, but the conditions of his practice forced him always to wait until the patient consulted him. Undoubtedly there had been an improvement in, and elaboration of, methods of diagnosis and treatment, but these methods were, generally speaking, confined to the hospital and specialist, upon whom fell the work which was the lot of the general practitioner in years gone by.

It was a fact that there had been an increase in the incidence of peptic ulcer during the past ten years but the increase was probably more apparent than real, because by modern methods of diagnosis, including x-ray examination cases which had been overlooked in the past were now rightly classified. As for vaccines he could not remember that he was in the habit of using them to any greater extent in 1934 than he did in 1924 but if the work in the surgery was properly organized the injection of such preparations called for no more time than the case in which advice and treatment were given by more usual methods. The number of confinements among his insured patients was considerably less in 1934 than it had been ten years previously. There had been some increase in the number of people suffering from minor nervous disorders but the treatment of the severer cases of psychoneurosis required a consultant of wide experience. As for the ageing of the population it was evident that the proportion of elderly people was increasing but in his experience many of those who had been in regular attendance at the surgery up to the age of 65 ceased after attaining that age. The institution of old age pensions had meant a falling off in that branch of the work.

In reply to Lord Amulree, the witness said that although hospitals and clinics had made serious inroads on general practice, this did not affect the income derived from in-

surance practice, it did affect, of course the income from private practice. Dr Dain asked the witness if he seriously maintained that it was not more important to be able to diagnose the case of appendicitis when first seen than it was to be able to take the appendix out when the case came for operation. The witness replied that there had been no alteration in that respect. That principle had existed as long as the clinician had been at work. Dr Dain further asked if the witness maintained that no further treatment was required after a patient had had gastro-enterostomy done in hospital. The witness replied that he was not prepared to say that. He agreed that he had had cases which required continuous dieting and treatment for several years after gastro-enterostomy. He further agreed that any such case would require treatment for at least a year, but cases which had not been properly diagnosed and operated on would probably require it for many years.

Mr T LINDSAY of the Ministry's staff, answered a few questions by Dr Dain regarding the figures set out in the Ministry's case. Some of the questions were so complicated that the witness had to resort to a calculating ruler to arrive at the answers.

This concluded the Ministry's case.

IAC Case Further Evidence

Dr DAIN said that in view of the evidence given by the last two medical witnesses, he wished to call a practitioner at present in practice who could speak from experience on the points raised by the Ministry.

Dr D G GREENFIELD of Rushden, Northants gave evidence that he had been in practice in that district for 35 years, at first single handed, and now he had two partners. During the last three years his insurance practice had comprised a list of 3,400. When he was single handed, with a list of 2,000, he estimated his surgery hours in the morning to be an hour and a half now with 3,400 the morning surgery hours for all three doctors were two hours each. Dr Harvey had said that all his serious cases of rheumatic fever went to hospital. He did not suppose that he himself had sent a case of rheumatic fever to hospital for the last five years. For medical purposes other than diagnosis he had no hospital provision in his district. With regard to young people coming to the doctor for advice while in health, it was and was likely to be, the case increasingly that young people would come for counsel as to the sort of training they should undergo. The witnesses on the other side had referred to varicose veins. Since the new treatment was instituted and his partners started doing this work there were seldom fewer than four or five people in the surgery on a Sunday morning undergoing this treatment or resting after it. He had not encouraged Sunday morning surgery work at all, only emergency cases being seen as a rule but Sunday morning was a suitable time for dealing with these troublesome cases with the result that there were always four or five of them on hand. In this instance at any rate modern treatment had not saved the general practitioner work though its results of course might save his successor a good deal of work in ten years time.

He was astonished to hear from the other witnesses that pernicious anaemia in their experience was so rare. He had nine cases under treatment in his practice at the present time. It was not a very rare disease. It seemed to be assumed that these people invariably went to hospital for their blood and haemoglobin estimations, but in fact in his practice a considerable number of these blood counts were done by the doctors themselves. These patients remained under treatment for many years, previously the patient with pernicious anaemia died within possibly two years. It was much the same with diabetes. He disagreed that diabetes was entirely for the expert. The treatment of the diabetic, requiring visits to the surgery was carried out by general practitioners and called for a very considerable amount of expert work. These people again lived on indefinitely, whereas when he was

early in practice young people who contracted diabetes were dead in a matter of months. He had five or six cases of diabetes at the moment. With regard to gastric ulcer, to pretend that modern surgical treatment had eliminated the need for medical work was obviously wrong. It was far too optimistic to suggest that people who had undergone operations for this complaint would require only six months' or a year's after-treatment. They came up year after year. Another point was the use of the microscope, he found his juniors using it a good many times a week. As for old age pensioners, certainly if they ceased to require a certificate they did not come quite so often, but many of them required a club certificate which, though not an insurance obligation, was given them, on the advice of the British Medical Association, as a matter of grace. In his practice women were still attended by the doctors for their confinements and without undue fear.

Dr Dain pointed out that the Ministry had offered no evidence on the question of practice expenses, and on Mr Harrison remarking, 'I have concluded my case,' Dr Dain rejoined that it was evident the Ministry did not wish to submit any evidence on that point, and to that extent the position was made clear.

Joint Conference of Approved Societies

Mr STANLEY L. DUFF said that he had been asked by the approved societies to submit some observations to the Court. The matter before the Court was between the doctors, as represented by the B.M.A. and the Minister, and by direction of the Court the memoranda submitted by each of the parties were not made available until the Court opened. On this account those for whom he spoke had not been able to submit any written statement. He was speaking for the group of industrial insurance societies, trade union societies, friendly societies, and other groups covering virtually the whole of the insured population of the country. It was the members of these approved societies who were the patients of the doctors.

Attention was drawn in the statement by the Insurance Acts Committee to the improvements in the medical service rendered to insured persons. The standard of medical service to which the insured person was entitled was that which could reasonably be expected to be rendered by the practitioner. The range of service implicit in the contract had remained virtually unaltered from 1924 until the present date. Any treatment outside that range had still to be obtained by the insured person from some other source and paid for usually by the insured person himself. The improvements referred to in the Committee's case were in the opinion of those for whom he spoke, merely bridging over certain defects which had been admitted to exist in the medical services rendered to insured persons in the early stages of the administration of the scheme. The fact that the service did more nearly approach the standard which it was originally intended to reach ought not to be regarded as a reason for attracting additional remuneration. The approved societies' view was that the additional complexities referred to in that part of the statement were partially responsible for the increased number of insured persons referred to hospitals by insurance practitioners.

Attention was also drawn in the I.A.C. memorandum to the increased incidence of certain diseases. The approved societies could agree from their experience of their records that that change had occurred. At the same time there were certain other diseases and complaints which had greatly diminished in exactly the same period as these new diseases and new phases of old diseases had appeared. Reference was also made to the ageing of the population, but it was important to bear in mind that since 1925 certificates had not been required in respect of insured persons above 65. The pension

figures—and it was because of the Pensions Act that this change in the age of health insurance liability came about—at December 31, 1935, showed that the number of insured persons between 65 and 70 qualifying for pension was 475,000 men and 85,000 women. The number of persons of those ages entitled to medical benefit must necessarily be greater because the qualifying conditions for pensions were more onerous. Therefore it was safe to estimate that the number of persons between 65 and 70 in receipt of medical benefit who at one time had been entitled to medical certificates and did not now receive them exceeded 560,000. Whatever the Committee might choose to say the fact remained that at the last Court of Inquiry work in connexion with certification was heavily stressed. It was stated "There is nothing corresponding to this in private practice, and this important and burdensome service should be recognized by remuneration. Therefore as the result of the legislation of 1925 a definite relief had been afforded to the doctor.

References to R.M.O.s

Reference was made in the Committee's statement to the number of insured persons who were referred by approved societies to regional medical officers. It was true that there had been concerted action between the Committee and the approved societies with a view to reducing the number of these references. But it was the duty of the approved societies to determine the title to benefit on the evidence before it. The majority of references now occurring arose from dubiety in the minds of approved society officers as to the value or completeness of the medical certificates submitted by insured persons. From the experience of a number of approved societies he was bound to say that the doubt which prompted the reference had in a large number of cases been substantiated.

He wished to say a word or two about the attractiveness of insurance practice to doctors. In the Committee's statement it was said that young doctors found more attractive avenues elsewhere. But between 1924 and the present date the number of insurance practitioners had increased by 4,387. This increase was entirely disproportionate to the increase in number of insured persons during the same period. The security offered by insurance practice, containing as it did the nucleus of a reasonable competence, was proving attractive. It was not necessary to improve the remuneration in order to recruit or retain doctors of the type necessary to sustain the service at what was an improving level.

It was said that with regard to the juveniles the doctors' duties would be to a considerable extent preventive and advisory. If it were thought that that ideal would be realized no objection would be raised by the approved societies to the payment of a substantial fee in respect of such young persons. Unfortunately experience showed that there was no reality in the relationship portrayed. Young persons to an even greater extent than older ones would not in practice go to a doctor unless they had some illness or disability. In the group of insured persons within the contemplated new age the proportion who would encounter illness or disability was obviously considerably less than in the more advanced ages. The statement that employers would require notification as to the condition of health of their employees was not borne out by the facts. Large employers of labour who usually required a certificate of that kind had their own medical officers to deal with that type of case. It was said that it was not now disputed that one general capitation fee should be applied to all insured persons including the juveniles shortly to be brought into medical benefit. In the view of the majority of approved societies a markedly lower capitation fee should be associated with juveniles. The only merit of the uniform fee rested upon administrative consideration.

Tribute to the Service

Mr Duff added that despite anything he had said he must not be regarded as reflecting on the quality of the service rendered by insurance practitioners. On the part of approved societies there was no general dissatisfaction with the service. The tributes to the doctors which were set out at the beginning of the I.A.C. case could be multiplied many times over. The service generally deserved more commendation than was occasionally awarded to it in ill-informed quarters. He emphasized the fact that the basic capitation fee which obtained at the inception of the scheme in 1912 was 7s 3d. Various increases due to economic changes in the war resulted in the figure mounting spasmodically to 11s in 1920, and as the figure of 11s had been brought before the Court it was only right that the earlier figure of 7s 3d should not be absent from the Court's mind. The approved societies were satisfied that the opinion expressed in the Ministry's memorandum that a case existed for a reduction in the capitation fee on the grounds there set out and to the extent there mentioned was well founded.

At the end of his statement Mr Duff was asked some questions by Dr Dain, but he protested that he was not speaking as a witness and it had not been possible for the approved societies in the short time available to assemble the material they would have wished. In reply to Dr Dain Mr Duff agreed that it was not invariably the case that large employers had their own medical officer for the purpose of examining employees and giving certificates. Asked whether he had any knowledge of the extent to which young persons went to doctors he said that as secretary of the National Conference of Friendly Societies he was familiar with the operations of those societies which gave benefit to young persons of these ages, and the amount of benefit so given was less than at other corresponding age groups. He had no knowledge of the matter except in so far as related to sick pay.

You made a point that the doctor is liable to give a full general practitioner service. Do you agree that if that service takes longer time he might reasonably ask for more money?—If it is done as thoroughly and takes longer that is a legitimate point for you to advance.

If it requires a greater number of services would that entitle the doctor to ask for more money?—It is difficult to know how new services can arise when there is no change in the range of service.

National Association of Insurance Committees

Mr T. A. E. SPEARING said that the National Association of Insurance Committees had no statement to make. They were quite content with the submission by the Ministry of Health.

Closing Speech for the Ministry

Mr T. D. HARRISON, solicitor and legal adviser to the Ministry, delivered his closing speech on behalf of the Ministry and dealt with a number of detailed and technical points which had been presented in evidence. With regard to the nature of the services he said that contradictory evidence had been offered on the one hand by doctors for the Ministry and on the other by one doctor for the Committee and where doctors disagreed it would be foolish for him to intervene. He must leave the evidence before the Court. He dealt at length with the evidence given with regard to motoring costs and urged that the Ministry's case was based on more authentic figures than that of the other side. Unless it could be shown that doctors were such a peculiar class that they must not be assumed to be like the rest of the population in car usage, it was probable that the same change in the type of car had taken place in the medical profession as among the general public.

Closing Speech for the Insurance Acts Committee

Dr DAIN said that he wanted to take his case in two sections first to deal with figures and then to say a little about the service. There were three important numerical accessible factors. The first was the fall in the cost of living as to which there was no disagreement and which entailed possibly a reduction of the capitation fee by 5d. On the question of practice expenses, in 1924 there were only available certain suggestions as to what practice expenses probably were, and these were obtained from a few practices and related in part to a war period. Later a number of doctors were asked to submit their accounts for the period of three years. Then there was a gap and afterwards another period of three years was taken and it was found that the proportion of practice expenses remained about the same in the two periods. On the basis of these carefully collected statistics practice expenses were found to be about one third of the gross earnings of the practice, whereas they had previously expected them to be about one-fourth. Thus it was possible to correct the figures given under this head to the Court in 1924, and no other figures had been submitted. Although the sample was not a large one, it produced information which they thought was sufficient.

He hoped it would not seem rude to those who had given evidence on motoring costs if he took no further point on it, but left the information to the Court, saying only that the evidence on the side of the Ministry was of a theoretical character and bore no relation to the actual expenses of doctors. If practice expenses in general were taken as 33 per cent. instead of 25 per cent., and the proportion of motoring expenses was reduced to one third, he scarcely needed to point out that the effect on the capitation fee of a small alteration in the cost of transport would not be material in the final calculation. Accepting the increase from 25 per cent. to 33 per cent., which was not rebutted this would mean an addition of 9d on the 9s and would bring the figure of 8s 7d up to 9s 4d.

Coming next to items of work done he thought it had been established that the Ministry did not maintain that its figures were an accurate record of service given. They maintained that certain comparisons were possible but they did not maintain that by the method of calculation they could possibly represent the total amount of work. He wanted first to take what the Ministry agreed could be compared. He was very disappointed that practically they had had only two figures from the Ministry, one at the beginning and the other at the end of the period, with no intermediate figures. If a larger set of figures could have been produced to the Court it would have made it possible to discover whether there was a year-to-year fluctuation in services rendered owing to changes in the type of sickness and whether there was a change in the proportion of attendances to visits as between different types of practice and in different areas. The Committee's figures showed that there was such a change, and he had hoped they would be confirmed by figures from the Ministry.

The Argument from Figures

Dr Dain then addressed himself to the discrepancy between the Ministry's figure of 3.72 for items of service undertaken and the Committee's figure of just over 5, and after pointing out certain necessary adjustments of the Ministry's figure said that the Committee based its case on the accuracy of the recording of the services. What credit could be placed on the figures obtained as the Committee had obtained them? The Government actuary had stated in evidence that on the size of the sample which the Committee had taken it was a good sample and that on distribution it probably could not be challenged. When spread over such an area as was taken

it was not likely to be seriously wrong. No criticism had been raised, or at any rate substantiated, as to the Committee's sampling, and the only point of criticism was that the people who had collected the figures were volunteers who, knowing the purpose for which the statistics were being collected, were likely to set down the maximum services. But that was exactly what they wanted done—namely, the recording of every item of service—and he hoped they had obtained it. He believed that the volunteers for this job had done it very well, and that over this long period of years valuable and accurate results had obtained by the co-operation of a large number of doctors in busy practices, doing recording work which was uncongenial, irksome, and trying at the end of the day. The irksomeness of such a task might well be the reason why many did not volunteer. He agreed that there was the occasional danger, as in the case Dr Paterson had referred to, that a man might enter up as both an attendance and a visit the one item of service, but he could not expect that that was very likely to happen.

If it was admitted that their volunteers were more likely to record all the services than the "conscripted" men of the Ministry, then their figures were the very ones required for the present Inquiry. They had been criticized for comparing their 1922 figures with their 1936 figures on the ground that they were prepared according to a different method, but if a different method yielded greater accuracy it was perfectly justifiable to admit it frankly, and he believed the Committee was offering to the Court a more accurate analysis than it was able to offer to the Court of 1924. He believed indeed that the profession had suffered a heavy financial disability on account of the inevitable understatement made thirteen years ago, and they were now looking for its rectification.

The difference between the 3.75 average services in 1922 and the 4.69 in 1924 was partly due to improved methods, but also reflected increased work. Those of them who had been in practice at that period were particularly conscious of that jump long before any figures were available to prove it, and the later figures showed that it had been maintained at the higher level ever since, and had steadily tended to go upward. This was supported by a 24 per cent. rise in prescriptions between 1922 and 1924, while over the whole period of years it was only 80 per cent. The point had been made that there was something wrong about this increased frequency, and that the profession itself was engaged in an effort to stop it. But when regard was paid to the returns of work done it was found that the increase of work was greatest in the areas of high frequency of prescription which confirmed them in their argument that there was a definite relation between script frequency and work done.

On the evidence of the work done to-day he submitted that the claim had been established for an increase of 3s. or of 3s. 3d., according to whether the Ministry's method of weighting was adopted or not, bringing up the fee to 12s. 4d. or 12s. 7d. With regard to the 14-16 age group he agreed that it was very difficult to evaluate this service with any accuracy. Statistics really did not help. The profession was amazed at the "half-price" suggestion. When the Ministry made its offer it was immediately represented by a Press headline "Cut Rates for Juveniles." The only figures produced to the Court were from fifty-nine practices, and the only criteria were that these were the practices nearest the average for the Ministry's selection. Obviously no account had been taken of the very important fact that there were certain districts and practices in which there would be practically no juveniles, the houses in these areas being occupied mostly by middle-aged people, and there were other areas on the new estates where the numbers of these people would be comparatively very large. Unless there had been a proper weighting of the practices chosen to allow of this factor, he submitted that fifty-nine out of

18,000 doctors was an infinitesimal and possibly a very misleading sample. With what must be a diminishing group in an ageing population, it was not unreasonable to balance it up in a general way without attempting to fix any very accurate figure.

General Considerations

Dr Dain continued

But numbers are only numbers, and this is a service dealing with human beings. Numbers are no evidence of good service, and it is the service that matters. The medical profession is more interested in the good service of insurance practice than any other body of people. The insured persons who get the service should also be interested to get a good service. We regard this service as nearly the ideal method of providing medical attention for the people. The fact that the patient can choose his own doctor, that the relationship between doctor and patient is not interfered with, that there does not come between patient and doctor any monetary consideration to limit either the patient's access or the doctor's ability to work for the patient—all this makes the service a kind of key service. We agree that it is incomplete; we should like to see it completed in several ways, but it is the one big service in which medical knowledge, medical skill, and the progress won in clinical medicine is brought into contact with the individual. The family doctor is the person who can take new experiences and new knowledge to the individual. When the service is extended in scope so that it includes consultant services and procedures such as pathological examinations, blood counts, and x-ray investigations, it will be a complete health service. We have always stood for the best service we could give to the insured person. As a small example out of our own money we have provided a fund so that if a practitioner is getting old and incompetent we can on application get his practice disposed of and put him on a pension. He himself has contributed nothing to it, the Ministry has contributed nothing, we have done it out of our own funds. We have also made arrangements for doctors to purchase their practices—all with the idea of improving the status of the service.

On the question of relationship with our friends on the other side if there has been any alteration since 1924 it has been in the direction of improvement and we welcome the expression of appreciation with which Mr Harrison opened his original case. When I looked at the Ministry's case and found that while their advocate thoroughly appreciated our service he thought the way to recognize it was to take 1s. off the capitation fee, I wondered why he should pat us on the back with one hand and deplete our purses with the other. But I do not find that Mr Harrison pressed the demand for 1s. reduction.

We came to this Inquiry prepared to offer the Court all the information at our disposal and we think that we have advanced arguments which will appeal to those who constitute this tribunal and who are not themselves concerned in the service. I said that the standard of work is up. I do not claim any more money on the standard but it should not be depreciated in any way. The number of complaints against the service is certainly very low. There is one other factor to which I referred in my opening speech—namely the economic position of the country. We have chosen this moment to bring forward our case because as I explained before we have been prevented from doing so earlier on account of the economic crisis of a few years ago and its repercussions. But we have seen the condition of the country improving and it has improved to a point at which we think that our remuneration might well be reconsidered. We are content to leave our case to the Court's decision. We hope we have argued it fairly and that we have not put forward any statement which we have not supported. We have made no extreme or extravagant claims but have given reasons for every factor we have advanced. I put it to you that it is as important to the public as it is to us that a service of this size and importance should be properly paid and I ask with

confidence that you will encourage the sound and wholesome development of this service and our further efforts in that respect by the amount of your award

Close of the Inquiry

Lord AMULREE expressed to the parties the Courts high appreciation of the cases they had presented so fairly and of the evidence of the witnesses who had been called. He could only at this stage express the hope that the decision the Court would presently announce would give satisfaction

GENERAL MEDICAL COUNCIL

DISCIPLINARY PROCEEDINGS

Motor Car Offences

The Council considered the case of ERNEST STANLEY O'SULLIVAN registered as of Dunowen Gardens, Cliftonville Belfast who was summoned on the charge that he was convicted at the Stockton Police Court in 1933 of being under the influence of drink whilst in charge of a motor car, and at the City Police Court, Newcastle on Tyne in May, 1936 of the following offences: driving a motor car while under the influence of drink, driving a motor car in a manner which was dangerous to the public and using a motor car when the brakes were not in good and efficient working order. In each instance he had pleaded guilty.

Consideration of the case had been postponed from the winter session the solicitor having been unable to establish communication with Dr O'Sullivan or to serve the notice of inquiry.

Mr Oswald Hempson for the Medical Defence Union on behalf of Dr O'Sullivan expressed his regret that he had not notified his change of address and that his wife while he was away ill had, out of mistaken kindness kept from him all knowledge of the first warning received. Since 1936 Dr O'Sullivan had been a total abstainer and he now gave an assurance that this would continue. At the time of the 1936 convictions he had been worried and unwell. He was but a young man and he hoped the Council would decide to give him another chance.

Testimonials as to character were submitted from a resident magistrate, a medical practitioner, two ministers of religion and a solicitor, with a number of testimonials as to his professional standing.

The President, in announcing the decision of the Council said the convictions indicated habits which were a discredit to the doctor and to the profession. To give him an opportunity of reconsidering his attitude and changing his habits the case would be adjourned to May 1938 and before that meeting he would be required to produce the names of persons of standing who could testify as to his habits in the interval.

The next case concerned WILLIAM DALE LAWTON registered as of Princess Road Moss Side Manchester. The charge listed seven misdemeanours in respect of which he had been convicted between August 1922, and December 1936 of obstructing the highway by a motor car without lights of being drunk whilst in charge of a motor car of driving in a manner dangerous to the public and of being drunk.

Mr Oswald Hempson defending, asked for the indulgence of the Council on behalf of Dr Lawton who was 75 years of age and had been in his present practice for thirty three years although, owing to advancing years and ill health he had given up a good deal of that practice. He emphasized that during the period in question there was a gap of eleven years during which there had been no offence by Dr Lawton. Mr Hempson was not prepared to give an undertaking of total abstinence on behalf of Dr Lawton because although he was not a heavy drinker he had been in the habit of taking a certain amount of alcohol and those who were looking

after him had advised that it might be detrimental to his health if he broke it off altogether. Dr Lawton was maintaining the practice in the hope that his son who would sit for his final examination in September next might be able to succeed him. Indeed that would be the only chance the son would have of securing a practice except by means of a loan because Dr Lawton had been unable to make provision to assist his son further. If the Council took the extreme step of removing Dr Lawton's name from the Register he would be ruined and the chances of his son would be prejudiced.

Letters to show that Dr Lawton was held in high esteem by his patients were read also a letter from a practitioner in Manchester who had attended him during his illnesses, and who stated that he seemed to benefit by a little stimulant.

Dr Lawton undertook that if the Council would extend clemency there would be no further cause for complaint. He would not touch alcohol outside his private house and that which he did take would be in accordance with medical advice.

The President announced that the convictions alleged against Dr Lawton had been proved to the satisfaction of the Council but the Council was willing to exercise leniency and to postpone judgement until May 1938. Before that date Dr Lawton would be required to send to the Registrar for the use of the Council the names of persons of standing who would testify to his habits and conduct in the interval.

Other Convictions

The Council considered the case of DAVID WILLIAM JONES registered as of Belsize Lane London N.W. the charge against him being that in October 1936 he was convicted at the City of Birmingham Police Court of obtaining credit to the amount of £29 5s 6d from the London Midland and Scottish Railway Company by fraud and was sentenced to four months imprisonment in the second division and that his appeal on December 1 1936 against the conviction was dismissed.

The defendant was not represented by counsel.

The solicitor to the Council explained that the credit was obtained by fraud other than false pretences. There was a female defendant in the proceedings and at the Queen's Hotel Birmingham she presented a "dud" cheque which Dr Jones it was alleged knew to be such. When a question was raised Dr Jones said they would call on the following day and settle the account but they were not seen again. The defendant had said he was financially embarrassed at the time and if he could get the money due to him the account could be paid.

Dr Jones asked that the evidence of a lady witness the lady friend mentioned in the case might be taken *in camera*.

The President asked why the witness should not be called in the ordinary way.

Dr Jones: If you decide not to hear her *in camera* I am afraid I cannot call her.

The Council having heard the evidence *in camera*.

The President addressing Dr Jones said: The Council does not propose to-day to pronounce judgement but you will be required to attend here twelve months later in the May session of 1938 to furnish for the information of the Council the names of professional persons and other persons of standing in order to testify their knowledge of your habits and conduct in the interval. You will receive notice of the date of the meeting and the Council will proceed to pronounce judgement.

A charge was considered against ALFRED EDWARD LAWSON registered as of Redcot March that after pleading guilty he was convicted at Uxbridge Petty Sessions of having obtained from a firm of jewellers by means of false pretences two diamond rings valued at £52 with intent to defraud. He was sentenced to two months imprisonment in the second division and that subsequent appeals to the Middlesex Sessions and High Court respectively were dismissed.

The Council's solicitor handed in the records of the conviction and other particulars, which showed that Dr Vawser was formerly a medical officer of the Royal Air Force and that at one time he had suffered from a motor accident which had affected him ever since.

Mr Oswald Hempson defending referred to the appeals the last one of which was dealt with purely on the technical ground that Dr Vawser had pleaded guilty at the petty sessions. Dr Vawser had pleaded guilty as the result of a suggestion made to him that it would be to his advantage but Mr Hempson had no hesitation in suggesting that had he been legally advised at the time he would not have done so. It was the first occasion on which he had ever been before a tribunal and previously he had borne an unimpeachable character. He had not fully appreciated that the charge to which he had pleaded guilty involved fraud. He had secured the rings from Messrs Waddington and Sons, which were said to be valued at £52, and had intended them for his wife. In order to secure a valuation, and having understood that pawnbrokers gave a third of the value, he had pawned them and had received £20 for the two rings, from which he had assumed that they were worth about £60. Following a serious motor accident in Irak in 1929 in which he had sustained a fractured skull, he had since been subject to a little muddleheadedness in times of stress. At the time of the alleged misdemeanours his wife was ill, he was attending many cases in an epidemic, and he himself became ill and had to remain in bed for some days. Owing to the conviction against him he had had to resign his commission. Since then he had tried to earn a living as a locum tenens' testimonials to his abilities were submitted. At the moment he was seeking to build up a practice. He had already lost one career which had been full of promise and if his name were erased from the Register it would mean the end of everything for him. At the time he had obtained the rings he was in uniform and had given his proper name and address as he had done when he had pawned them. Could it be assumed from that that he was trying to defraud somebody, particularly having regard to the fact that at this time he had money behind him?

The Council found the conviction to be proved to its satisfaction but did not direct the Registrar to erase the name.

Alleged Irregular Certification

The Council considered the case of JOSEPH SHIBKO registered as of Prince of Wales Road, Swansea who appeared to answer the charge that being a medical practitioner he on four dates in 1936 signed and issued a certificate of incapacity for work for a person described as William Ward, whereas he had not seen or examined the said William Ward on any of such dates or at all, which certificates were untrue misleading, and improper.

The Council's solicitor supported the charge and the defendant was represented by Mr W. A. Macfarlane instructed by Messrs Le Brasseur and Oakley on behalf of the London and Counties Medical Protection Society.

Mr Harper outlined the facts of the case. He said the wife of William Ward had produced certificates saying her husband was suffering from neuritis and she received a considerable sum of money from the authorities. In her statement she said she went to Dr Shibko for the certificates and he, without any questions gave them to her. Dr Shibko in reply to this, denied that he gave any certificate without having first seen the person whom he took to be the person named on it. Mrs Ward had been charged at the police court with obtaining £33 wrongfully and she had pleaded guilty.

Mrs Ward was called and said she had attended Dr Shibko's surgery for herself and her children. She called on the doctor and asked him to give a certificate that her husband was unable to work. He did so without asking any questions and on the other dates mentioned he gave further certificates. The doctor did not visit her house at all and he never saw her husband. She went to the surgery by herself, unaccompanied by her husband or any other man.

In cross-examination the witness said her husband was not an insurance patient of Dr Shibko. She admitted that

William Ward had not had an illness for about nine years. On one of the certificates the doctor wrote that William Ward was suffering from neuritis and bronchitis. She gave no particulars and did not even mention that her husband was coughing.

Asked by Mr Macfarlane if she had told her husband anything about the certificates she replied: "No, I am the bad one, and I have suffered for it. Nobody besides myself knew I was getting the certificates." Counsel suggested that the witness had got someone to go with her to the doctor impersonating her husband, and that when she was found out she kept quiet about that. She denied this saying there was nobody who could go with her. She admitted that she herself wrote a statement to show to the relieving officer, signing it with the name of a person who had been dead some time.

William Ward in the witness box said he had not lost a day's work through sickness for nine or ten years. All that time he had not seen a doctor and he had never visited Dr Shibko's surgery, neither had he authorized anybody to call there on his behalf. He had received unemployment relief in 1935, but he was not sick. The first time he saw Dr Shibko was at the police court during the proceedings against his wife, and then Dr Shibko said, "I feel sure I have seen you in my surgery." His reply was, "You're a liar."

Dr Shibko examined by Mr Macfarlane said he had been interested in local government work for many years and was quite familiar with the way in which the Poor Law work was done by the public assistance authorities. He had on his list in Swansea between 1800 and 1900 insured persons and he had about 300 families under the Public Medical Service. In addition he had a private practice, which was worth about £500 a year made up of small fees.

He explained his methods of dealing with the various forms of certification in use and the keeping of records. He emphatically denied that the four certificates in question were given without his having seen the person named on them. He had never done such a thing, and would never think of giving a certificate without examination. Asked whether it was practicable to prove the identity of a person coming for a certificate he admitted that this was not possible. He had a large practice and he at first assumed that William Ward was one of his insured patients but the fact that he was not would be discovered by his clerk when he went through the entries for record purposes. At the police court he thought he recognized William Ward, and he had a vivid recollection concerning one of the dates mentioned in the charge because he had then asked why the applicant should come to him, seeing that his surgery was three and a half miles from the applicant's home. He had already mentioned that point to Mrs Ward. If the man on that occasion was not William Ward it was somebody remarkably like him. He repeated that he never gave a certificate to Mrs Ward for her husband without seeing him or somebody who was represented to be him. It was his invariable rule. People sometimes asked him for certificates without his having seen the person concerned but they never got them. He had never been under any misapprehension as to the legal or professional consequences of doing otherwise. There was some conversation at the police court as to whether he had sufficient evidence to establish a charge of personation, but his recollection was not clear enough for that.

In reply to Sir George Newman, the defendant said he kept no clinical records in cases where he gave ordinary certificates without treatment. There was no such record in any of the four instances mentioned in the case. He added in answer to Mr Macfarlane that medical practitioners were not bound to keep a record of certificates except national insurance certificates.

Statements were read to the Council from influential gentlemen in Swansea and district all of which contained evidence of Dr Shibko's very high character and his exemplary professional conduct. One was from an ex-mayor of Swansea and chairman of the Unemployment Assistance Advisory Committee another from a clergyman who had met Dr

Shibko frequently in the homes of his patients, and four were from members of the medical profession. They included the assistant physician in charge of the out-patient department at Swansea General Hospital, the public medical officer and public vaccinator of Swansea and an honorary surgeon to Swansea Hospital; they referred to the great understanding and sympathy with which he treated his patients and his high regard for medical ethics.

Mr Leonard Williams, relieving officer in Swansea since October, 1935, gave evidence. He said that Dr Shibko was still the Poor Law medical officer for the district with which witness was concerned. He added that sometimes he acted on certificates by doctors which were not on the proper relief forms. Replying to questions he said that if a husband was not fit to make an application for relief he would accept an application from a wife. Mrs. Ward had said that her husband was not fit to make application.

Mr Macfarlane, addressing the Council on behalf of Dr Shibko, emphasized the high reputation of his client, and said that the charge against him was based on evidence which, to say the least, was from a very unreliable source. Those who had written to support him had referred specifically to his regard for the ethics of the profession, the fact that he kept most careful records and the care which he devoted to his patients. Dr Shibko had a considerable insurance service and a private practice, and he kept records of treatments and prescriptions. In the case before the Council a man had visited his surgery and had said that he was William Ward, living at a certain address. Dr Shibko happened to know that address, and had assumed that the man was on his list—quite a reasonable assumption. The man complained of a pain in his arm, which was said to be neuritis, and said that he could not go to work. In a district such as Swansea a man ran the risk of losing his job if he stayed away. The question was whether he had a reasonable excuse for not attending his work. It might be difficult for a doctor to be sure about neuritis. At any rate the certificate was to the effect that the man was at present unable to follow his employment. That certificate appeared to have been regarded as good for three months, whereas it should have been regarded as good merely for that particular day. Dr Shibko had said that the form of the certificate was not the form which he used in cases of application for relief. On the other hand Mrs. Ward said she had specifically stated that it was an application for relief. The account she had given was so fantastic as to be incredible. She had said that she had merely asked the doctor to be kind enough to give a certificate to say that her husband could not work, that she had not said what was the matter and that the doctor had not asked questions but apparently had accepted that the trouble was neuritis. Subsequently other certificates were alleged to have been given. Did it seem credible that the doctor should have made out such certificates to a man he had never seen and at the request of a woman to whom he was under no obligation whatever? Was it likely that he would imperil his position in that way?

The Council deliberated in private after which the President announced that the statements alleged against Dr Shibko in the charge had not been proved to the satisfaction of the Council.

Sequel to Divorce Proceedings

The next case considered was that concerning BARDWELL ERDEN TENISON MOSSE, registered as of King Street, Kings Lynn, who was charged that being a registered medical practitioner he had committed adultery with Ethel Gregory Johnson, a married woman of which adultery he had been found guilty by divorce decrees which had been made absolute in the case of Johnson v. Johnson and Mosse and Tenison Mosse v. Tenison Mosse in which he was co-respondent and respondent respectively, and that he stood in professional relationship with Mrs. Johnson and/or her husband.

The Council's solicitor read extracts from some of the divorce court proceedings and other facts dealing with the case. He also put forward a list of professional attendances

on Mr and Mrs Johnson between 1929 and June 1935 and said that for August and September 1935 there were records of three attendances which were not admitted by Dr Mosse.

Mr J. A. Parsons, the senior partner of a firm of solicitors of Kings Lynn who had acted for Dr Humphreys and Dr Tenison Mosse during their partnership at Kings Lynn, recognized Dr Mosse's handwriting in record books showing attendance on Mr Johnson on three occasions in 1935. In cross-examination Mr Macfarlane suggested there was nothing to show that the entries in the books were made on the actual day on which the patient was given attention. Witness replied that he could only speak of what the books showed. He added that the partnership between Dr Mosse and Dr Humphreys was dissolved as from September 23, 1935 by a transfer from Dr Mosse to an incoming partner.

Dr Mosse then gave evidence and said he was living at Wells, Somerset. The divorce proceedings referred to having been made absolute, he had married the lady who was previously Mrs. Johnson on December 23, 1936. His evidence was that there had been no adultery while he was practising as a doctor. Since he had dissolved partnership with Dr Humphreys in September 1935, he had not been engaged in the practice of medicine but had been selling motor cars. He had had a conversation with Mr Johnson in September 1935 and shortly afterwards had given up his practice. More recently he had engaged solicitors to write on his behalf to the Registrar of the General Medical Council because he had another medical partnership in view, and considered that it would not be fair to his prospective partner to enter into that partnership without having an inquiry by the Council, in view of the reports of the divorce proceedings.

He had first met Mrs. Johnson in 1927 socially but not professionally, when acting as locum tenens for his brother. Neither he nor Mrs. Johnson was a patient of his brother. In March 1928 he went into a partnership in Kings Lynn of which Mr and Mrs Johnson were partners and he had subsequently attended them professionally. He had also continued to meet them socially a great deal. In July 1935 he realized that he was in love with Mrs. Johnson. He had discussed the matter with her, the attraction was mutual and he had said at once that he must not attend her or her husband professionally. He had himself immediately taken steps to dispose of his share of the practice. It was his and his partner's custom to enter up the books from notes made by both of them and though some of the entries relating to the Johnsons were in his handwriting he had not given the attendance.

Replying to questions by members of the Council Dr Mosse agreed that it was merely coincidence that his partner was on duty at the surgery on the three occasions in August and September on which Mr Johnson had called there.

Mrs. Mosse, who was previously Mrs. Johnson, gave corroborative evidence.

Mr Macfarlane, in his address to the Council, emphasized that the only adultery ever alleged was from February 1936 onwards when Dr Mosse was not practising medicine. In his submission Dr Mosse had acted correctly in the matter so far as the profession was concerned. When he had desired to resume practice he had behaved with exemplary fairness to his prospective partner by refusing to enter into the partnership before having an inquiry into his matter.

The President, after the Council had deliberated in private, announced that the facts alleged in the charge had been proved to the satisfaction of the Council but that the Council had not judged Dr Mosse to have been guilty of infamous conduct in a professional respect.

Erasures from Dentists Register

On May 25 the Council considered reports and findings of the Dental Board in regard to five cases of dentists.

WILLIAM LAIRD, registered as of Gray's Hill, Bangor, Co. Down, Dentist 1921, was charged with having systematically canvassed either personally or by means of an agent for the purpose of procuring patients. Mr Laird did not appear.

JAMES SHARPLES HOPWOOD registered as of Flinton Road Urmston Lancs Dentist 1921 was charged in two cases with having transmitted a dental letter containing untrue and improper certificates to an approved society and wrongfully obtaining payment of the society's grant Mr Hopwood did not appear but a letter was read from him pleading mitigation on the ground of ill health and domestic difficulties He said that he had made full reparation

ALBERT EDWARD LLOYD registered as of North Drive, Cleveleys, Blackpool, Dentist 1921 was charged with having transmitted a dental letter containing untrue and improper certificates and wrongfully obtaining payment of the society's grant also with accepting a dental letter and carrying out certain work after he knew that he had been declared unsuitable for service in connexion with dental benefit A letter was read from Mr Lloyd in his absence but the Council's solicitor said that the points it raised were irrelevant to the charge

EDWIN SPENCER TEBBUTT registered as of Finsbury Square London, L.D.S.R.C.S.Eng. was charged with having been convicted on September 4 1936 at Hastings police court of being drunk, on September 17 at the same court of being guilty while drunk of disorderly behaviour, and on February 10 1937 of being drunk and disorderly Mr Tebbutt did not appear, but by the Council's permission he was represented by a friend who pleaded on his behalf that he had not practised for the last five years and that he had sustained heavy financial losses through no fault of his own. Reference was also made to much voluntary service in years gone by

JOHN KENNEDY SCOTLAND registered as of Millbrae Crescent Langside, Glasgow L.D.S.R.F.P.S.Glasg. was charged with having been convicted at the Sheriff Court of Lanarkshire of the following offence that on twenty occasions between May 26 and September 29 1936 he had presented to various chemists fabricated prescriptions and obtained from them quantities of morphine sulphate which he had not been duly authorized to procure Mr Scotland who did not appear but was represented by a solicitor sent a letter in which he pleaded war injury He declared that it was a bitter commentary on the four and a half years service he had given to his country and the blood he had shed that he should not be allowed as he wished to do to withdraw voluntarily from the Register but should be compelled to this fresh publicity

After a brief session *in camera* in each case the President announced that the Registrar of the Dental Board had been instructed to erase the names of these five practitioners from the Register

Restoration

The President announced after a further session *in camera* that the name of Thomas Ross Graham had been restored to the Dentists Register

Cases Postponed from Previous Sessions

The case was considered of Dr WILLIAM MERVYN CROFTON registered as of Park Square London who at a previous session in May 1935 had been found to have made a speech at a meeting of ophthalmic opticians in which he had made claims of an extravagant nature as to the benefits likely to result if the method of therapeutic immunization practised by him at an establishment known as the Antego Laboratory were generally practised and had accented the inability of other members of his profession to obtain comparable results also to have thereby advertised for the purpose of obtaining patients and promoting his own professional advantage or in the alternative to have sanctioned or acquiesced in the publication of notices commending or directing attention to his professional skill knowledge, services or qualifications and/or depreciating those of others The Council had postponed judgement for two years and at the end of one year expected testimonials as to his conduct with special reference to advertising, and further testimonials at the end of the second year An account of the hearing appeared in the Supplement of June 8 1935

Dr Crofton now appeared and was also represented by a solicitor who said however that he had nothing to add to the testimonials which had been put in These testimonials from Dr J F Halls Dally Dr Archibald G Buchanan and others stated that to the knowledge of the writers Dr

Crofton's professional conduct had been without reproach The Medical Defence Union which had brought the complaint in the first instance, did not appear

After a brief consideration *in camera* the President announced that the Council did not see fit to erase Dr Crofton's name from the Medical Register Thereupon Dr Crofton remarking Then I am a professionally free man walked up to the President's table and handed the Registrar a document which he said was a formal complaint about the way in which the Council had dealt with his case He was understood to declare that it had shown bias of a heinous and unprofessional kind and I am prepared to maintain that The President said The case is closed

The case of Dr WILLIAM DOUGLAS registered as of Goldhawk Road Shepherd's Bush W., who had been found to have been convicted twice in 1935 for driving a motor car whilst under the influence of drink (Supplement June 13 1936 p 320), came up for judgement Dr Douglas put in three testimonials as to his conduct in the interval, and the Council did not see fit to erase his name

The same course was taken with Dr DAVID DAVIDSON WATSON registered as of King Street Wakefield, who had had two convictions, one in 1933 for driving a motor car whilst under the influence of drink and the other in 1936 for being in charge of a motor car in a like condition Dr Watson put in four testimonials and the Council did not see fit to erase his name

The Council considered the case of Dr WALTER CAMPBELL, registered as of Jeffrey Street, Edinburgh who was summoned to appear on the charge that in 1931 he had been convicted at Cupar of being in charge of a motor car whilst under the influence of drink and in the same year at Dunfermline of a technical offence with regard to a motor car that in 1935 he had been convicted at Hull of driving a car without due care and attention and in 1936 at Leeds of driving a car whilst under the influence of drink and of driving a car in a manner dangerous to the public This case came forward at the previous session, when as Dr Campbell did not appear it was adjourned (Supplement December 12 1936 p 319)

The Council's solicitor (Mr Harper) said that Dr Campbell was not present and he could not prove that he had had the notice of inquiry served on him. Four letters had been returned through the Dead Letter Office and he had been unable to ascertain Dr Campbell's whereabouts. The offences were of a kind which the Council generally dealt with by putting the offender after hearing what he had to say on probation but there was no opportunity of learning what was Dr Campbell's answer to the charge

The Council decided to hear the case in the absence of the respondent, and the certificates of the convictions were put in

After a long deliberation *in camera* extending over an hour and a quarter, the President announced that the charges had been proved to the satisfaction of the Council but as Dr Campbell was not present it was not possible to say anything directly to him The Council had postponed judgement until November next, before which date Dr Campbell would be required to furnish for the information of the Council evidence as to his conduct in the interval, and he would be well advised to appear

Election of Committees

The following were elected members of the Executive Committee

Sir Robert Bolam Sir H. Brackenbury Mr Eason Mr Edington Mr Johnstone Mr Miles Sir T. Myles Sir George Newman, Mr Sinclair Dr Stopford Dr Sydney Smith, and Dr Tidy The Dental Executive Committee was the same as above with the addition of Mr Sheridan.

The Finance Committee was elected as follows

Mr Eason Mr Miles Dr Magennis Sir George Newman

The following were elected to constitute the Pharmacopoeia Committee

Dr Bone Dr Brocklehurst, Sir Farquhar Buzzard, Dr Campbell Dr Kidd Mr Leathes Sir Kave Le Fleming Dr Matthew Dr Magennis Dr Moorhead Dr Sydney Smith, Dr Tidy

The following constituted the Dental Education and Examination Committee

Mr Bishop Harman, Dr Coffey Mr McGowan, Mr Rilot Mr Sheridan Dr Waterston

GENERAL MEDICAL COUNCIL EXECUTIVE

A meeting of the Executive Committee of the General Medical Council on February 22 resolved that the diplomas in medicine and surgery granted by the Punjab University on or after February 25, 1930, should be recognized for the time being under Section 13 of the Medical Act, 1886, and the holders of these diplomas (L M S M B, B S, M D M S) be entitled to registration in the Colonial List. Any qualification granted on or after January 7, 1918, must have been registered in the province.

At the same meeting of the Committee letters from the Home Office were reported notifying the withdrawal from five practitioners of the authority granted by the regulations made under the Dangerous Drugs Act, 1920. Amended rules of the Central Midwives Board regulating the procedure of the Board on complaints relating to the conduct of midwives were before the Committee which did not however, desire to make any representations on the proposed amendments.

The expenditure of the General Medical Council during 1936 was £10,031, of which £2,709 represented the fees and expenses of members.

Correspondence

THE CAPITATION FEE

SIR.—A point which so far has not been raised at the present inquiry is the remuneration per attendance with the present capitation fee. I kept records for the Panel Committee some time ago and I had the curiosity to work this out. Without distinguishing between surgeries and visits but adding up everything received for capitation fee dispensing and mileage I found that every time I saw a panel patient whether at the surgery or at his home say six miles away I received roughly one shilling. If the Government or anyone else thinks that this is adequate the sooner they are left to their own devices the better. With a little advertisement we could make a better living by selling a mixture of peppermint and coloured water guaranteed a cure for all human ills. Nor would this entail a long and costly training—I am etc.,
South Godstone May 30 H E GIBSON

DISPENSING CAPITATION FEE

SIR.—I was very glad to see Dr Burt's letter in the *Supplement* of May 22 (p. 308). I have not seen any county with the average dispensing fee so low as that allowed to rural practitioners for supply of drugs to insured persons. Several factors seem to have been overlooked.

If all those carrying out panel practice had to supply the drugs and accessories such as cotton wool lint bandages etc. themselves there would have been an outcry long ago. It is because we are in the minority so scattered and so isolated that we are unable to make a combined effort to correct this lamentable state of affairs. Nor can we purchase our drugs at anything like the prices available to chemists who not only buy in bulk but receive a greater discount. Every practitioner who has to supply medicines to his insured patients is usually far from the source of supply thus involving extra freight charges. In addition there is often the cost of delivery to the patients themselves which is very rarely paid by the latter. The fee does not cover the cost of drugs let alone the time for dispensing them often of far more consideration than anything else. In addition to the foregoing, the primary cost of drugs has been steadily increasing the last few months, many of the commoner and essential ones being over 50 per cent. higher to-day than they were six months ago.

At the Annual Panel Conference on October 22 last Dr Jonas replied to two members who brought up this subject. 'The question of the capitation fee must take precedence of any question of the rural practitioner's remuneration for his drugs whereat the two members gracefully crept back into their shells. The two fees are entirely different matters the one being for services rendered the other for products supplied. It would be quite useless for me to inform my druggists that I will only pay them 1s 2d per lb for glycerin even though the present price is 1s 9d (1s 2d is the drug tariff rate).

As there are no chemists in the majority of rural areas I wonder if the G M C would sanction the sale of cosmetics etc. by country doctors to make up for what they lose as a chemist friend once told me on the medicines supplied to insured persons—I am, etc.,

N Devon May 25

Among the recipients of knighthood in the Coronation Honours List is Mr William Marchbank Marshall secretary to the Scottish Association of Insurance Committee. Mr Marshall has been closely associated with the medical services in Scotland since the inception of the National Health Insurance Act. He is clerk to the Lanarkshire Panel Committee, secretary of the Lanarkshire Medical Practitioners' Union and clerk and treasurer to the Insurance Committee for the County of Lanark. He is also chairman of the Advisory Distribution Committee of the Department of Health. As a member of the Government Committee on Scottish Health Services he played an influential part in the deliberations of that body. Mr Marshall is a well known figure in the public life of the West of Scotland and his many friends in the medical profession will be glad to see this signal recognition of his services.

Proposed Alterations of Areas of Berks, Bucks, and Oxford, Gloucestershire, Dorset and West Hants, Southern, and Surrey Branches

Notice is hereby given by the Council of the Association to
all concerned of the following proposed alterations of
areas, which have been approved by the Branches and
Divisions concerned

Berks, Bucks, and Oxford Branch

To cede to the proposed new Aldershot and Basingstoke
Division of the Southern Branch that part of the rural
district of Kingsclere and Whitchurch at present in the
area of the Reading Division

To cede to the Gloucestershire Branch the eastern part
of the County of Gloucester at present in the area of
the Oxford Division

BUCKINGHAMSHIRE DIVISION

(No change)

OXFORD DIVISION

To cede to the Gloucestershire Branch the eastern part
of the County of Gloucester at present in the area of
the Oxford Division

READING DIVISION

To cede to the proposed new Aldershot and Basingstoke
Division of the Southern Branch that part of the rural
district of Kingsclere and Whitchurch at present in the
area of the Reading Division

Dorset and West Hants Branch

To cede to the Southampton Division of the Southern
Branch that part of the rural district of New Forest at
present in the area of the Bournemouth Division of the
Dorset and West Hants Branch

WEST DORSET DIVISION

(No change)

Gloucestershire Branch

To receive the eastern part of the county of Gloucester
at present in the area of the Oxford Division of the Berks,
Bucks, and Oxford Branch

Southern Branch

To receive the following additional areas

(a) That part of the rural district of New Forest at
present in the Bournemouth Division of the Dorset and
West Hants Branch,

(b) that part of the rural district of Kingsclere and
Whitchurch at present in the area of the Reading Division
of the Berks, Bucks, and Oxford Branch,

(c) municipal borough of Aldershot, the urban districts
of Farnborough and Fleet, and that part of the rural
district of Hartley Wintney lying east of and including
the civil parishes of Crondall, Crookham, Elvetham, and
Eversley—at present in the area of the Guildford Division
of the Surrey Branch

ALDERSHOT AND BASINGSTOKE DIVISION

New Division to be formed of area as follows

(a) Municipal borough of Aldershot, and urban dis-
tricts of Farnborough and Fleet—at present in the area
of the Guildford Division of the Surrey Branch,

(b) municipal borough of Basingstoke, and rural dis-
trict of Basingstoke—at present in the area of the
Winchester Division of the Southern Branch,

(c) rural district of Hartley Wintney—at present in the
areas of the Guildford Division of the Surrey Branch and
the Winchester Division of the Southern Branch,

(d) rural district of Kingsclere and Whitchurch—at
present in the areas of the Reading Division of the Berks,
Bucks, and Oxford Branch and the Winchester Division of
the Southern Branch

GUERNSEY AND ALDERNEY DIVISION

(No change)

ISLE OF WIGHT DIVISION

(No change)

JERSEY DIVISION

(No change)

PORTSMOUTH DIVISION

To receive the following additional areas

(a) Those parts of the rural districts of Droxford and
Petersfield which are at present in the area of the Win-
chester Division of the Southern Branch

(b) that part of the urban district of Fareham which is
at present in the area of the Southampton Division of
the Southern Branch.

SOUTHAMPTON DIVISION

(1) To receive the following additional areas

(a) Municipal borough of Romsey, and those parts of
the municipal borough of Eastleigh and the rural district
of Romsey and Stockbridge which are at present in the
area of the Winchester Division of the Southern Branch

(b) that part of the rural district of New Forest which
is at present in the area of the Bournemouth Division of the
Dorset and West Hants Branch.

(2) To cede to the Portsmouth Division of the Southern
Branch that part of the urban district of Fareham which
is at present in the area of the Southampton Division

WINCHESTER DIVISION

To cede the following areas

(a) Municipal borough of Basingstoke rural district
of Basingstoke and those parts of the rural districts of
Hartley Wintney and Kingsclere and Whitchurch which
are at present within its area—to the proposed new Alder-
shot and Basingstoke Division of the Southern Branch

(b) those parts of the rural district of Droxford and
Petersfield which are at present within its area—to the
Portsmouth Division of the Southern Branch,

(c) municipal borough of Romsey, and those parts of the municipal borough of Eastleigh and the rural district of Romsey and Stockbridge which are at present within its area—to the Southampton Division of the Southern Branch

Surrey Branch

To cede the following areas

(a) Municipal borough of Aldershot, urban districts of Farnborough and Fleet, and that part of the rural district of Hartley Wintney lying east of and including the civil parishes of Crondall, Crookham, Elvetham, and Eversley which are at present within its area—to the proposed new Aldershot and Basingstoke Division of the Southern Branch

CROYDON DIVISION

(1) To receive that part of the urban district of Coulsdon and Purley which is at present in the area of the Reigate Division of the Surrey Branch

(2) To cede those parts of the urban district of Banstead and of the rural district of Godstone which are at present within its area—to the Reigate Division of the Surrey Branch

GUILDFORD DIVISION

To cede the following areas

(a) The urban district of Walton and Weybridge—to the Kingston-on-Thames Division of the Surrey Branch,

(b) municipal borough of Aldershot, urban districts of Farnborough and Fleet, and that part of the rural district of Hartley Wintney lying east of and including the civil parishes of Crondall, Crookham, Elvetham and Eversley, at present within its area—to the proposed new Aldershot and Basingstoke Division of the Southern Branch

KINGSTON-ON THAMES DIVISION

(1) To receive that part of the urban district of Walton and Weybridge which is at present within the area of the Guildford Division of the Surrey Branch

(2) To cede that part of the urban district of Banstead which is at present within its area—to the Reigate Division of the Surrey Branch

REIGATE DIVISION

(1) To receive the following additional areas

(a) Those parts of the urban district of Banstead which are at present within the areas of the Croydon and Kingston-on-Thames Divisions of the Surrey Branch,

(b) that part of the rural district of Godstone which is at present within the area of the Croydon Division of the Surrey Branch

(2) To cede that part of the urban district of Coulsdon and Purley which is at present within its area—to the Croydon Division of the Surrey Branch

RICHMOND DIVISION

(No change)

Any member affected by these proposals and objecting thereto is requested to write to the Medical Secretary by July 5 stating the objection and the ground therefor

G C ANDERSON
Medical Secretary

July 23 Fri	Meetings of Sections etc., Belfast

Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition in respect of 1938. The following are the regulations governing the award.

1 The Prize is established by the Council of the British Medical Association for the promotion of systematic observation research and record in general practice. It includes a money award of the value of fifty guineas.

2 Any member of the Association who is engaged in general practice is eligible to compete for the Prize.

3 The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not therefore be omitted when it bears directly on their results, their interpretations, and their conclusions.

4 Essays or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1 not later than December 31, 1937. The Prize will be awarded at the Annual General Meeting of the Association to be held in July 1938.

5 No study or essay that has been published in the medical press or elsewhere will be considered eligible for the Prize and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the Prize.

6 If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7 Each essay must be typewritten or printed, must be distinguished by a motto and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

8 The writer of the essay to whom the Prize is awarded may on the initiative of the Science Committee be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9 Inquiries relative to the Prize should be addressed to the Medical Secretary.

Katherine Bishop Harman Prize

The Council of the British Medical Association is prepared to consider an award of the Katherine Bishop Harman Prize, of the value of £75, in the year 1938. The purpose of the prize, founded in 1926, is the encouragement of study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child bearing. It will be awarded for the best essay submitted in open competition competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1938 but will be offered again in the year next following this decision and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, it must be distinguished by a motto and accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Medical Secretary (to whom inquiries may be sent), B.M.A. House, Tavistock Square, London, W.C.1, not later than December 31, 1937.

Meetings of Branches and Divisions

KENT BRANCH EAST KENT DIVISION

At a joint meeting of the East Kent Division and the Isle of Thanet Public Medical Service at Cliftonville on April 29, with the chairman of the Division Mr W. E. C. WYNNE in the chair, Dr R. W. DURAND (Assistant Medical Secretary) gave an address on "Public Medical Services: Their Influence on the Future of General Practice." He said that the public was becoming increasingly health-minded. There was a growing tendency for State intervention in medical matters in response to demands from the lay public. A public medical service which could offer a full and complete service including preventive measures would help to combat unnecessary duplication of medical services. Anyone in receipt of a living wage could afford a public medical service subscription. The service should not attempt to cater (by low subscription rates) for persons entitled to public assistance. To do so was merely to offer charity to the local authorities who were responsible for the medical care of such persons. It was most important, if an efficient public medical service was to be provided, that the subscription rates should not be too low. They should if anything, be slightly above the national health insurance capitation fee, with which the profession had expressed its dissatisfaction. It had to be remembered that a public medical service was a voluntary organization and the patients would therefore include a higher proportion of bad risks than under a compulsory scheme such as the national health insurance scheme. The friendly societies should be invited to co-operate with the service but preferential rates should not be granted to their members. Dr Durand deprecated also the acceptance of juveniles at lower rates than adults and pointed out that the juvenile was on the whole a greater contract risk than the adult. On economic grounds it might be argued that there should be a lower subscription rate for juveniles but the fairest arrangement to meet this would be the adoption of a graduated scale of subscriptions varying according to the number of subscribers in the family whether juvenile or adult. He offered constructive criticism of the rules and organization of the Isle of Thanet Public Medical Service and made concrete suggestions for their improvement. This advice was amplified in the course of a long discussion in which members of the Division and of the service took part. The meeting closed with a hearty vote of thanks to Dr Durand for his interesting address and for his valuable help and advice.

SOUTH WALES AND MONMOUTHSHIRE BRANCH SOUTH WEST WALES DIVISION

At a meeting of the South-West Wales Division held at Carmarthen on April 28, Dr DANIEL T. DAVIES delivered a British Medical Association Lecture on "The Influence of the Mind in Organic Structural Disease." He pointed out that the division of disease into two classes, organic and functional was inadequate because a number of diseases such as peptic ulcer and high blood pressure existed which should not be assigned to either category. Dr Davies maintained that peptic ulcer was an example of a disease in which the mind acting through the central nervous system might perhaps be the originator. Experimental ulcer formation in animals which had not been possible until recently had held up investigations but it was now known that ulcers could be made to appear in animals in forty-eight hours and to heal in three weeks. This knowledge had now been applied to the human in whom it could be shown that ulcers formed often within a few days of the occurrence of an anxiety even where ulcers had been removed by operation previously. Similarly ulcers which were healing might relapse if the patient underwent some fresh mental strain. An interesting and instructive lecture closed with a hearty vote of thanks to Dr Davies for his address on the motion of Dr ABRAHAM THOMAS seconded by Dr ERNEST JONES.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Therapeutics and Pharmacology—Tues, 5 p.m. Annual General Meeting Election of Officers and Council for 1937-8 Paper by Dr A Loeser (Freiburg) Hyperthyroidism and the Thyrotropic Hormone of the Pituitary

Section of Ophthalmology—Fri 5 p.m. Annual General Meeting Election of Officers and Council for 1937-8 Paper by Mr E F King Epithelial Growths of the Conjunctiva and Cornea

HARVEIAN SOCIETY OF LONDON—At Connaught Rooms, Great Queen Street, WC Thurs 7.30 p.m. Buckton Browne Annual Banquet

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY—At 11 Chandos Street W Thurs 8.30 p.m. Dr T A Ross The Psychological Approach.

POST-GRADUATE NEWS

A post graduate course of weekly lectures in urology began at St Paul's Hospital for Urological and Skin Diseases Endell Street Holborn WC on May 19 and will be continued on Wednesdays, June 9, 16, 23 and 30 at 4 p.m. Registered medical practitioners and students are invited to attend any branch of the work in which they are interested. Details of the remaining lectures will be published week by week in the post graduate diary column of the *Supplement*.

A lecture on the theory and practice of contraception will be given to medical practitioners and medical students who have completed their gynaecological course at the Walworth Women's Welfare Centre 153a East Street SE 17 on Friday June 11 at 6 p.m. Practical demonstrations will be given on Friday June 18 at 6 p.m. and 7 p.m. Those attending a demonstration should bring rubber gloves.

standards recommended in the report of the Technical Commission, and of the differences observed as regards the state of nutrition of people in different countries or regions, and how far such differences are due to climate.

The work of the Technical Commission on nutrition has aroused the greatest interest in the medical world and beyond its borders. Its report will inspire to a great extent the work of the forthcoming intergovernmental conferences on rural hygiene, as well as various other activities, and the Health Committee feels that the procedure followed up to the present in the study of nutrition has produced valuable results in a comparatively short time. The Technical Commission will remain the pivot of all activity in this field, and for specific studies it will have the benefit of the collaboration of groups of specialists, or can apply for authoritative opinions to national authorities, leading scientific institutions, learned societies, and institutes and schools of hygiene, which last are carrying out certain field studies on the Commission's behalf.

DISSOCIATION AND REPRESSION

LECTURE BY PROFESSOR McDougall

'The Relations between Dissociation and Repression' was the subject of a lecture delivered by Professor WILLIAM McDougall, professor of psychology, Duke University, N.C., before the Medical Section of the British Psychological Society at a meeting held at Tavistock Clinic on May 26. Dr H. CRICHTON-MILLER was in the chair.

Professor McDougall began by saying that the words "dissociation" and "repression" were widely used, but in the main by different authors. He had no doubt that both were needed, each standing for phenomena of a different order. Janet's doctrine of dissociation had had a very wide influence, being propagated by William James and by many Harvard teachers. To these and other psychologists dissociation remained the master principle of all psychology, and they were sceptical about repression. Others, however, pointed to repression as a process which seemed to lie at the back of many neurotic symptoms. Freud had never admitted the need for the word 'dissociation,' either as a term descriptive of neurotic symptoms or as standing for an explanatory theory, and in this he seemed to be followed by most of those who called themselves psychoanalysts in the stricter sense as well as others like Jung and Adler, who had derived their doctrines from Freud by way of emendation of his teaching. This continuing division of opinion was in part a consequence of personal antagonism between Janet and Freud, it might properly be regarded as a symptom of the sickness of psychology.

The lecturer himself regarded both conceptions—dissociation and repression, as necessary and a considerable number of the more eclectically minded psychologists, who seemed to be more abundant in this country than in any other, used both words as descriptive terms and recognized the need for at least two corresponding theories of interpretation of the facts. At the time he wrote his *Outline of Abnormal Psychology* he confidently assumed the reality and importance of dissociative symptoms and the need for some adequate theory of dissociation. That was natural considering his affiliations with Harvard. He was frankly a disciple of William James. He had read Janet intensively before he had ever heard of the work of Freud, but when he came to study Freud he did not hesitate to recognize that in his doctrine of repression Freud had got hold of something of vast importance that had almost if not entirely escaped the penetration of Janet and others. He attempted in his book to hold the balance true and to give due recognition and weight both to dissociation and repression, treating repression as a dynamic factor which in many cases prepared the way and led to dissociation, but he was very conscious at that time that

he had not got to the bottom of a very complex problem of fundamental importance. He had gradually come to realize that under the one term 'dissociation' he, like almost all who had used the word, had been confounding at least two things which required to be distinguished—broadly, dissociation and disintegration.

Processes of Mind Organization

The first step towards the clearing up of this complex problem must be to distinguish as clearly as possible the various different meanings of 'dissociation' as used by different writers, and in disentangling the meanings he was helped by keeping before his mind the distinguishable conditions of mental integrity. In the main the study of the abnormal went forward without regard of an explicit kind to the principles of harmonious integration. If one regarded the development and structure of the mind as the product of the operation of the all-powerful principle of association, as the nineteenth century psychologists did, then one naturally saw in dissociation the one all-prevailing principle of mental disorder. Some such logic as that seemed implicitly to have pervaded Janet's doctrine of dissociation.

Few were content nowadays with the old association doctrine of mental organization, but there was much uncertainty as to what principles must replace or accompany association as the organizing processes by which the sound mind became a harmoniously working entity or unity. He had distinguished two great aspects of mind organization. The first was the logical structure, growing in two ways, mainly by the differentiation of the germs of mental structure or mental dispositions, but occasionally also by the fusion of such systems achieved by acts of synthetic apperception. The second aspect was what he called the historical aspect of the total structure of the mind, consisting of innumerable acts of association resulting in the formation of links between those units of structure which grew in the two ways just described.

If there were, then, these three distinct processes of mind growth—differentiation, fusion, associative links—logically one ought to look for three corresponding processes of failure or breakdown. He thought such breakdowns did occur, resulting from the undoing of these processes, but the one he wished especially to deal with was the breakdown of the historical structure resulting in what he understood by dissociation. He had come across cases of complete absence of memory of any particular past experience, complete amnesia so far as concrete facts were concerned, but complete retention of the use of language and the understanding of things. Such an individual found his chief trouble in practical life that he did not know the names of things, and names, of course were attached to things by associative processes. On the other hand there were also rare cases of arrest of function of the logical structure of the mind as well as the associative structure, and in such cases the individual became like a newborn babe understanding nothing. The structure was not destroyed in either type of case, but somehow ceased to function, ceased to be flooded with energy.

Relation of Dominance and Subordination

Under this view of dissociation mind was not regarded as made up of aggregations of atoms of sensation or feeling or any 'stuff' of consciousness, but rather as consisting of distinguishable units of structure which might be described most conveniently as mental dispositions. These units of structure became linked with one another with a multitude of links of association. It was a fair assumption that the structure of the mind as he had described it hitherto could be validly translated into terms of neural or cerebral structure, these 'dispositions' being regarded as functional groups of neurons and naturally one could assume that mental dissociation

meant some kind of impairment or locking, partial or complete, of these neural cross-connexions

This was combined with a much more questionable assumption—namely, that neural continuity was the ground of the unity of consciousness. This might be valid, and it was so natural an assumption that it had been made by a number of authors apparently without realizing that it was speculative. This last assumption was perhaps better stated in a more modern form—that one condition of the unity of consciousness was continuity of the field of energy changes going on in the brain at any one moment—and it was in that form that the assumption was commonly made by the latest school of German psychology, which put forward the very questionable doctrine of isomorphism.

Professor McDougall went on to say that when he came to write his *Outline of Abnormal Psychology* he found it necessary to mention a fourth kind of functional relation between various parts of the total structure of the mind, one which clearly obtained in normal functioning—the relation, namely, of dominance and subordination. This relation made of the total structure not merely a vast complex system of units reciprocally influencing one another, but a unity in a further and higher sense. It was the maintenance and functioning of these relations of dominance and subordination which integrated the whole organization of the mind and made it a harmoniously working unity.

These relations were strictly dynamic ones. It was difficult to suggest any adequate picture of corresponding relations between neural systems. They were essentially moral relations, or at any rate mental. Perhaps they had no neural equivalents. It was because of this that he had felt compelled to describe the mind as made up of monads, meaning mental units, relatively independent psychic entities. The integration of a personality must be regarded as consisting in the main in the maintenance in one harmonious whole of the system of dynamic relations of dominance and subordination. The other structure relations might then be properly regarded as adjuvant, as instrumental aids to or conditions of integration or the functioning of the whole personality.

A Military Analogy

At this stage the theory of dissociation and the theory of repression began to be connected. It could not be impossible to reconcile and combine these two ways of thinking. Professor McDougall took the analogy of an army, and used it several times during the remainder of his lecture. He imagined a great army spread over a wide front with many compact units, each of which had its own internal organization. Such was the multiple structure. These units in turn were organized within larger units to be likened to the mental systems. Then he supposed that for routine communications between these units and systems a multitude of field telephones would be installed; these would represent what he had called the historical structure, the multitude of associative links. So long as the units maintained their normal internal organization and the telephone wires were in good condition the army was a whole, each unit playing its part. It exemplified so long as those conditions obtained the principle of holism as set forth so elegantly by General Smuts or what was called in America "organicism." But if for any reason such as an electrical storm the telephone system was impaired it would represent what happened in the mind during relative dissociation as in sleep, hypnosis, anaesthesia, alcoholic influence and fatigue. Actual rupture of the wires between the systems would represent local cerebral dissociation cutting out some special function or allied group of functions.

But the more effective function of the telephonic system did not make the army a unitary thing. If the wires carried only information about the state and doings of each unit or gossip or backchat or argumentation as

might be imagined in an army run on communistic principles, no high form of unity would be attained. Such unity in a highly complex structure could perhaps only be found in the hierarchical system of dominance and subordination. The telephonic system might function well even though the army was in a state of anarchy that would mean extreme disorder resulting from the breakdown of the hierarchical system. The lower form of unity represented by free communication between units would be there; the higher form of unity would be lacking. In other words, there would be disintegration and disharmony without dissociation.

What was it in the mind that corresponded to the hierarchical organization in the army? It was a moral relation of authority on the one side and obedience on the other. The best example of this dynamic relation was that between the hypnotist and his subject. It had no physical compulsion, nor even the threat of it, it was purely a moral compulsion, and yet a dynamic relation of the most effective kind. The authority of the higher members of the mind system implied communication with the subordinate units. Did the higher members control the lower through the associative mechanisms? He was strongly inclined to the view that that was not the whole case. He liked the idea as expressed in Upton Sinclair's phrase "mental radio" or, in more familiar terms, telepathic communication, as indicating the means whereby these moral relations were maintained. But if that seemed too speculative there were various possibilities in more ordinary modes of communication.

Maintenance of the Mental Hierarchy

Given some means of communication through which these relations of dominance and subordination were maintained, how was the authority or 'prestige' to be conceived? Here again a modification of the military analogy would help. A commander-in-chief or warrior king was endowed with his power, in part as a result of his individual qualities, but also in part by reason of tradition which in the human organism might be paralleled by heredity, and in part by custom, which might be paralleled by habit. The commander-in-chief represented or symbolized the force or energy of the whole system and could bring it to bear upon any one part. Perhaps a soviet army with its hierarchy of officials, afforded a closer analogy of the hierarchical organization of the mind. The main point he wished to insist on was the reality of the double system: first the associative links which maintained the communication between all parts and, secondly, the dynamic relations of dominance and subordination which alone secured integration of all the mental functions.

When these relations broke down there appeared in one form or another, not mere dissociation but other disintegrations or possibly it would be better to use the term disharmony as more descriptive. These two very different forms of disorder—dissociation and repression—each comprising a multitude of minor forms—were commonly classed together and both were called dissociation by one party and conflict or repression by the other. But the units of an army might disagree or refuse to obey orders—that was conflict without loss of contact—such units might be overwhelmed and rendered ineffective and that was repression. Such rebellion or mutiny might result in the breakdown of communications, the rebels becoming isolated physically as well as morally, which was repression leading to dissociation, with consequent disintegration. In either case the isolated unit might continue to struggle as well as it could against the forces which had overwhelmed it or might be spurred to renewed activity by favourable circumstances. He rejected Janet's original use of the term "dissociation" as descriptive of the falling away of mental atoms in the whole of consciousness. He accepted localized cerebral dissociation underlying various functional defects but he admitted that there was a case to be made out against

this form of dissociation, and he distinguished between disharmony and disintegration, the latter in many cases bringing in dissociation as a secondary result of conflict and repression.

In conclusion, Professor McDougall said that he was inclined to support the view that, although conflict and repression played a part in bringing about all such symptoms as amnesias and anaesthesias, actual cerebral dissociation was produced in all such cases, he went further, and argued that in some cases dissociation was directly produced without proceeding to conflict or repression. He also claimed that the clear distinction of the three forms of structural relation which he had mentioned, and of the fourth or dynamic relation of dominance and subordination which he had stressed, might possibly furnish a clue to the interpretation of all functional disorders.

Reports of Societies

AIR CONDITIONING

At a combined meeting of the Sections of Epidemiology and State Medicine and Medicine of the Royal Society of Medicine on May 28, with Surgeon Captain S. F. DUDLEY in the chair, the subject of air conditioning was dealt with from various points of view.

Ventilation

Mr R. FREDERICK, a specialist research worker in the Admiralty, discussed ventilation and its investigation. The study of ventilation in naval establishments and on H.M. ships, he said, was centralized at the Royal Naval Medical School, Greenwich to which samples of air and appropriate records were sent. Sometimes however, these samples had to be examined at their place of origin, and for this purpose a transportable laboratory was used, the various equipment of which he described and exhibited to the meeting.

The determination of carbon dioxide gave a reliable and quick means of finding out the respiratory impurity. A proportion of 12 parts per 10,000 was quite harmless. Even if the respiratory carbon dioxide in a room increased to 200 parts per 10,000 he was quite sure nobody would be conscious of it. At 250 parts it might be noticed a little. Only when the carbon dioxide exceeded 300 parts did the effect become appreciable, and experience of an atmosphere in which the respiratory impurity was 500 parts per 10,000 was not likely to be forgotten. The amount of air which must be supplied in an enclosed space to maintain a satisfactory condition was from 2,000 to 3,000 cu ft per man per hour, but this was being more and more regarded as only one factor in ventilation and it was realized that the question of floor space was no less important. The first requisite in air comfort was to have a moderate temperature and a moderate humidity. So far as temperature was concerned, in temperate climates the dry bulb was of chief interest, and in hot climates the wet. It had been suggested that the ideal was a temperature of 60° F. with a relative humidity of 50 per cent., but most people would find that too cold. The greatest agreement would be reached with temperatures of, for hard manual work 60° to 62° F., for sedentary work 62° to 64° F. for leisure conditions 64° to 66° F., with a relative humidity of 70 to 75 per cent. With regard to the wet bulb the figures of Haldane had been widely accepted in the still air a limit of 88° F. for sedentary work and 78° F. for hard work and in moving air corresponding limits of 93° and 85° F. Personally he thought these temperatures could be placed considerably higher.

The beneficial effect of air movement was due to its continual dispersal of the envelope of hot air between the clothes and the skin and the increased effect of convection currents. Apart from respiratory impurity, ventilation

conditions were assessed by the dry-bulb and the wet-bulb temperatures, the relative humidity and the air movement. In America the combined effect had been termed the "effective temperature," and a 'comfort zone' had been worked out, but for various reasons the use of such a combined method would be inapplicable in this country.

Air Conditioning in Factories

Mr C. W. PRICE of the Home Office referred first to the variety of conditions in industry. One ship's cabin was very like another, but "factory" was a comprehensive term, including all manner of works and mills in which the type of occupation imposed special conditions. While a proportion of factories could be air-conditioned, in any large number complete air conditioning was not within the realm of practical politics. A large number of plants for the partial conditioning of the air supply in factories had been installed, including plenum systems for supplying warm air in cold weather or cool air to furnace workers and the like. In addition, many exhausting plants were in service for extracting deleterious products in manufacturing processes. These extraction installations might be responsible for the whole of the ventilation in the rooms concerned, since the air extracted must be replaced.

The regulation of humidity in this country had not so far been adopted in the ordinary factory, thus there was nothing comparable with the more complete air-conditioning practice in the United States and Canada. If ordinary factories were adequately ventilated as the law required the problem of humidity was and would be regarded as of little significance. There was no requirement dealing with the cleanliness, the temperature, or the humidity of the air supplied, there must, however, be sufficient ventilation. The new Factories Bill would assist in bringing about some more efficient air conditioning in many workrooms. It was proposed to require the extraction where practicable of any dust whatsoever evolved in a manufacturing process if produced in substantial quantities, the present provisions were limited to harmful dusts. In not a few factories the advances made had already been very far-reaching, even in workrooms where peculiar conditions had to be overcome. Such good conditions might be found even where dangerous processes were carried on. Employers had been helpful, and had agreed to the necessary provision of higher standards of ventilation, while not neglecting temperature requirements. Attention had also been given to rates of air movement in particular positions in factories. Radiation was not an air-conditioning factor, but it was one, nevertheless, to be taken into account in any relative temperature evaluations. To what extent in factories should complete air conditioning be adopted or recommended? As regards workrooms where it might be adopted with advantage, it was doubtful whether the regulation of humidity as in complete conditioning was in general necessary. Mr Price briefly discussed the guidance given by recent physiological research.

Allergic Conditions and Air Purification

Professor E. M. FRAENKEL said that pollution of the air was of importance in different types of allergic complaints such as hay fever, asthma, and some cases of urticaria and eczema. The types of allergens which were effective were either outdoor or indoor impurities. The latter might be brought in by air or clothing or might consist of allergen-forming material already present (horsehair, feathers, woollen carpets, moulds, rugs, and the like) or of breakdown products formed by the action of moulds from innocuous indoor material. Air purification in the case of allergic patients was not identical with air conditioning. The walls and the contents of rooms air-conditioned for this purpose must be constructed of suitable material as indoor allergens were a more frequent source of trouble than those from outdoors. Impurities

from outside might be solid particles, fine droplets of moisture or even gases or vapours but were mostly a combination of two or more of these. Various methods such as filtration, freezing, washing or the influence of an electrostatic field had been devised for air purification. By means of a cinematograph film a special method of chemical and physical filtration devised by Professor Fraenkel for use in the diagnosis prophylaxis and treatment of suitable allergic cases was demonstrated. It was used in connexion with masks, sleeping bags, and cubicles, and the effect on an asthma subject sensitive to dog hairs was very strikingly shown.

The Psychological Factor in Ventilation

In the course of some informal discussion, in which Dr CLARK TROTTER and Surgeon Captain DUDLEY took part, Sir WELDON DALRYMPLE-CHAMPNEYS drew attention to the very considerable psychological factor in ventilation. In the Tropics it was found that white people stood up to moist heat badly, not only because they did not sweat satisfactorily, but because they were depressed by the idea that the atmosphere in which they were living was too hot and too moist. He had been struck while in tropical countries with the reactions of his companions to increasing heat and humidity, suggesting a psychological factor, and not to be accounted for on the basis of the purely physical condition. People of a more phlegmatic temperament stood up much better to increasing heat. The same thing was noticed in dug outs during the war. Some men could not endure them not owing to any claustrophobia, but because they thought the place was getting unhealthy. He had also noticed that in the cabins of ships in hot weather when the portholes had to be kept closed many people felt they were being suffocated. The importance of odours must also be remembered. Odours gave some people the impression of suffocation and made them acutely uncomfortable, though the actual physical conditions might be comparatively satisfactory.

Local News

ENGLAND AND WALES

Occupational Therapy

The Ladies Guild of the Hospital for Epilepsy and Paralysis Maida Vale W., organized a sherry party at Chester Terrace on May 26 when Dr Wilfred Harris gave an address on the subject of occupational therapy, mentioning that this hospital was one of the first in England other than mental hospitals to adopt this form of treatment. Dr Harris said that although occupational therapy was as old at least as Galen the great war brought about a revival of interest in the treatment on account of the large numbers of shell shocked patients and others wounded in mind and body for whom it offered a restoration of self-confidence stimulating a desire for renewed health. Occupational therapy was a system of devising occupations such as various handicrafts for patients who otherwise would have nothing to do and in whom idleness would aggravate the condition of depression or insomnia and weaken their already weak muscles and mental processes by disuse. In recent years occupational methods of treatment had been greatly developed and systematized in many of the large mental hospitals. Dr Harris mentioned in particular the hospital at Santpoort near Haarlem under Dr Kraus which he had recently visited and Chester County Hospital under Dr Grills where the recovery rate had gone up 43 per cent since the treatment was instituted. At both these large hospitals of from 1,500 to 1,700 patients from 95 to 98 per cent of the patients were constantly employed in handicrafts such as weaving, mat or rug making, knitting, sewing and embroidery, bookbinding, making paper flowers and bags

wood carving, basketry and raffia work besides kitchen and laundry work and outdoor occupations in the garden and on the farm.

TRAINED SUPERVISORS

As a result of this intensive system of occupational treatment, Dr Harris said it was found that noisy trouble, some, and destructive patients became quiet, social and productive, and hypnotics and other sedative drugs were much less required. It was not only for mental hospitals however, that occupational treatment was valuable for it had already been developed in Canada at the Toronto General Hospital and at the Astley Ainslie Convalescent Institution in Edinburgh. In America and Canada and in Scotland associations of occupational therapists had been formed, one was now being formed in England and schools were being started such as the Dorset House School at Clifton and that of Miss Tarrant and Miss Rivett in London where girl students attended lectures and were trained in the various handicrafts for two years before obtaining a diploma as teachers. A new profession was thus opening up for educated women for it was necessary to have trained supervision of the patients at their work to teach them and the nurses the handicrafts and to select occupations suitable to the different types of patients, some of whom required sedative and others stimulating methods or exercises for certain groups of muscles. Co-operation between the medical staff and the nurses on the one hand with the occupational therapist on the other was essential and the therapist should be supplied with details of the patients' ailments and their special needs. Games for small classes with the medicine ball and rhythmical physical exercises to music were an added feature of value to patients able to walk about. The essence of occupational therapy was to exercise the limbs in various ways and also to exercise the mind without the patient realizing that he was doing work or was being set a task. Thus it became recreation and instead of hours of boredom recurring daily which led to increasing depression and misery of outlook for the future the patients slept better and more naturally became brighter and happier, and felt that they were accomplishing something definite making something useful and perhaps might presently be started in a profitable trade.

The Maida Vale Hospital (whose new title is to be the 'St Marylebone Hospital for Nervous Diseases') is finding the system very advantageous. There are initial expenses in providing looms and materials but once started the treatment will more or less pay its way, even a small shop could be stocked or outside shops supplied with articles not retained in the hospital. Although the salary of a professional occupational therapist has to be paid an item on the other side is the not inconsiderable saving in the cost of hypnotic drugs. Dr Curran, psychiatrist at the Maida Vale Hospital added a few words on his experience in the psychiatric clinic attached to the Johns Hopkins Hospital and Miss Tarrant gave a demonstration of the work that was being and might be done. Over a hundred guests were present including several members of the committee of management of the hospital and the majority of the medical staff.

The London Bus Strike Health Aspects

The report of a Court of Inquiry concerning the stoppage of the London Central Omnibus Services 1937 has been issued as a White Paper (Cmd 5464 price 4d). It is signed by all three members of the Court—Mr John Forster, Sir Arthur Pugh and Mr Basil Sanderson—and paragraph 42 of their conclusions is devoted to the effect of working conditions upon the health of the men.

"The claim for the adoption of a maximum 7½ hour day was based fundamentally upon the contention that the work of the busmen is injurious to their health. Upon this question there was put before us in addition to certain statistics the evidence of three medical men. Neither the statistics nor the oral evidence convinced us that the claim of injury to health

was proved. If the medical evidence is examined it will be seen that both Dr S J Woodall and Dr H B W Morgan stated that the views which they held that there was a high incidence of illness among busmen were based more on general impressions than on any statistical evidence. Professor Culpin frankly admitted that he was not prepared to draw any conclusion from the results of the investigations he had made. Although we could not regard the evidence as affording any conclusive proof that the busmen's occupation is injurious to health we feel that a *prima facie* case was made out for further and immediate investigation by a properly qualified body specially constituted to deal with this important matter. We also feel that such a body should include experienced representatives of employers and of workers as well as medical men and other persons with the necessary technical qualifications to enable the matter to be freely explored. We are aware of the fact that there is already in being a subcommittee of the Industrial Health Research Board which is investigating the question whether gastric disease among busmen is greater than among other similar classes of workers. It is therefore necessary to point out that the question raised by the present dispute is one of the causation of disease among busmen rather than the question of comparative incidence of disease which is the question before that subcommittee."

Bristol Tuberculosis Conference

The twenty third annual conference of the National Association for the Prevention of Tuberculosis will be held in the physics classroom of the University of Bristol on Thursday, Friday, and Saturday, July 1, 2, and 3. The chief subjects for discussion are 'Propaganda and Publicity Methods,' to be opened by Dr Harley Williams,

Preventive Institutions, with Special Reference to Open-air Schools. (a) 'Environment,' to be opened by Dr Ralph P Williams and (b) Nutrition, to be opened by Professor J A Nixon. 'Equipment and Activities of a Tuberculosis Dispensary,' to be opened by Dr C J Campbell Faill. The discussions will take place on the first two days of the conference and will be followed by the annual meeting of the National Association, when it is hoped that Dr N D Bardswell will speak on the association's inquiry into tuberculosis in Cyprus. The third day will be devoted to visits to various institutions. Full particulars of the conference may be obtained from the acting secretary general, N.A.P.T., Tavistock House North, Tavistock Square, London, W C 1.

Queen Charlotte's Hospital

The annual report for 1936 of Queen Charlotte's Hospital records further satisfactory progress in the use of prontosil. In a series of eighty five cases of haemolytic streptococcal infection, sixty four of which were treated with this drug there were only three deaths. The mortality rate of 3.5 per cent in this series compares with a rate of 22.2 per cent from the opening of the Isolation Block to the end of 1935. Laboratory research demonstrated that the action of prontosil was probably due to the formation in the body of a simpler derivative. Clinically it was found that this substance produced a greater resistance to haemolytic streptococci, and for this and other reasons it is now being used in the wards. The report states that laboratory methods evolved to distinguish potentially dangerous streptococci from relatively harmless types have now become part of the ordinary routine, and that the hospital is prepared to undertake such investigation for any medical practitioners or public authorities who may require it. There has been a gratifying response from many parts of the country and large numbers of swabs have been received. By this means it is possible to determine whether a doctor or nurse in whose throats there may be reason to suspect the presence of haemolytic streptococci may safely attend a confinement. In the course of the year under review 3004 in patients were treated at the hospital, the largest number in the history of this institution. Of these patients 130 were single women with their first child.

SCOTLAND

Anti-tuberculosis Campaign in Scotland

The report of the Royal Victoria Hospital Tuberculosis Trust, which was summarized in the *Journal* of May 29 (p 1132), was presented to the annual meeting of subscribers to the Trust on May 26. Mr T J Carlyle Gifford, who presided, said that the Edinburgh tuberculosis scheme was now celebrating the fiftieth anniversary of its foundation by Sir Robert Philip in 1887, and it was a matter for regret that for the first time since the work of this Trust began Sir Robert Philip was unable to be present owing to illness. To-day a considerable amount of the Trust's resources was devoted to research. The chairman in referring to the Trust's dairy farm at Gracemount said that some other countries were far ahead of Britain in the provision of clean milk, and it might be said that under present conditions in Great Britain milk was one of the most dangerous foods. The Trust would therefore continue to press for improved conditions of milk production throughout the country. Professor Stockman, Glasgow, spoke of his early collaboration with Sir Robert Philip in research on tuberculosis and said that there had been many difficulties at first on account of prejudice, apathy, and wrong teaching. In considering the great work that had been done they must think not only of the decrease in the death rate from the disease but also of the accompanying decrease in suffering and impoverishment. Only two diseases were comparable with tuberculosis, one of these being scurvy and the other small-pox and both of these were rare now in this country. It was to be hoped that in another fifty or hundred years tuberculosis would be just as rarely encountered as these two were at the present time.

Research into Causes of Mental Illness

In the fifth annual report of the West of Scotland Neuro-Psychiatric Research Institute, Glasgow, it is stated that owing to the prior claims of other researches anaerobic bacteriological investigations were curtailed during the latter half of 1936. The study of flocculation reactions and their use in the serological diagnosis of syphilis has been actively pursued, and the production of a flocculation test which will be especially suitable for both sera and fluids is anticipated in the near future. Since July a systematic investigation of leucocyte activity in a patient suffering from the manic-depressive psychosis has been in progress. At the time of the preparation of the report, 429 examinations had already been made, covering a short normal phase followed by two months' depression and a gradual recovery of equilibrium. It is hoped to extend the observations over the whole cycle of the disease with a view to recording whether significant changes take place in the blood from one phase of the mental illness to another. Certain bacteriological and biochemical examinations have also been made on this case. Reviewing research activities in associated mental hospitals and institutions the report states that considerable progress has been made in the study of calcium metabolism in mental diseases. Investigations of the absorption rate of calcium as gluconate, administered intravenously, show encouraging results. At the conclusion of the report, the director, Dr W M Ford Robertson stresses the need for expansion of research into the causes of mental illness.

Glasgow Post Graduate Courses

A summer session for post graduate teaching has again been arranged under the auspices of the Glasgow Post-Graduate Medical Association. The facilities will fall chiefly into two divisions (a) general medical and surgical course and (b) clinical assistantships. During the last two weeks of August and the first two of September a whole time course for which an inclusive fee is charged,

will be conducted in some of the general and special hospitals. The course will include most of the subjects of interest to the general practitioner—the mornings being occupied with general medicine and surgical diagnosis and minor surgery in the Royal Infirmary and the Victoria Infirmary, and the afternoons with special subjects in the special hospitals or departments of the general hospitals, two subjects being dealt with each afternoon. In a number of the institutions taking part in the work of the association, clinical assistantships are available in the summer months as well as at other times. Full particulars may be had from the secretary, Glasgow Post-Graduate Medical Association, The University, Glasgow.

Correspondence

Trachoma from Spain

SIR—We are fully aware of the dangers of any infectious disease which could arise in a camp of 4,000 children, whether these diseases are those common to this country or peculiar to Spain.

Efficient co-operation exists between this camp and local authorities in Southampton and Winchester under supervision from the Ministry of Health. A completely equipped isolation unit was ready the day after the children arrived here, and is used as a diagnosis centre. Specimen material for bacteriological examinations is sent from here to local public health authorities for prompt investigation. There are five resident medical officers, who carry out a camp inspection daily at 7 a.m., when every child is seen. All sick children are referred immediately to a special medical tent.

With regard to ophthalmic examinations, one member of the staff has had a wide experience of trachoma as medical officer to the Royal Mail Company for examination of immigrants from Central Europe. He has not yet discovered any evidences of trachoma. As an extra precaution an ophthalmic surgeon from Southampton has kindly consented to see any special case.

It is so easy to rush into print and point out dangers which all medical men know to exist. It would be a matter of professional courtesy if Mr. A. F. MacCallan would communicate with me before disseminating his remarks. His letter to the *British Medical Journal* would not then have been necessary.—I am, etc.,

RICHARD W. TAYLOR

North Stoneham Camp, Eastleigh
Hants. May 29 Senior Medical Officer

SIR—As President of the International Organization against Trachoma Mr. A. F. MacCallan is clearly in a position to make *ex cathedra* statements as to the dangers of introducing this disease into England and to warn the Ministry of Health against so doing. It is unfortunate however that before a question was asked in the House of Lords about the matter with its inevitable repercussions and alarms Mr. MacCallan should not either have got in touch with any one of those directly concerned with the medical examination and care of the children or have made some inquiries as to the incidence of trachoma in the Basque district. He also appears to have assumed a trifle uncharitably that because the gentlemen who examined the children before embarkation in Bilbao were without special knowledge of ophthalmology they were therefore also lacking in the elements of common sense. We did in fact make it our first duty on arrival in Bilbao to inquire from the public health authorities as to the

incidence of trachoma in the Basque district, and found that of recent years it has been extremely low. This was confirmed by a Spanish ophthalmic surgeon of many years experience in Bilbao, who accompanied the children to England.

Mr. MacCallan's statement that trachoma is "practically universal" in certain provinces of Spain is apparently based on the report of Professor Soria (*XIII Congreso Ophthalmicum* 1929, 3, 113), and refers to the districts of Murcia, Almería, Valencia, and Castellón. It is, however, so exaggerated that it is surely based on a misunderstanding of Professor Soria's statistics. The figure 90 per cent which he gives refers not to the incidence of trachoma in the whole population, but to the percentage of eye cases which are trachomatous. Actually the highest incidence of trachoma in any province was 2 per cent of the population. The same source shows that the incidence in these districts was from twenty-five to fifty-five times as high in the neighbourhood of Bilbao, so that Mr. MacCallan's whole quotation is liable to be profoundly misleading.

It is hardly realized in this country how widely different from South and South East Spain are the circumstances both as regards climate and public health in the Basque district. Details of the medical care and examination of the children in England are given by Dr. Taylor.

We need hardly add that all those concerned are fully aware of their responsibility, and anxious to co-operate in necessary measures to prevent the spread of any infection that may occur.—We are, etc.,

RICHARD W. B. ELLIS

AUDREY E. RUSSELL

London, W.1 June 1

Treatment of Pharyngeal Carcinoma

SIR—I am much indebted to Mr. Musgrave Woodman (*Journal* May 22, p. 1089) for calling my attention to his experience in the use of inserted plaques. There must, however, be some fundamental difference in the technique we employ, for in the method which I described the plaques are at some distance from the skin wound, which is in fact, not exposed to any appreciable radiation. In my own cases the healing of the skin wound has been perfect, a very important consideration in patients of this class.

As to the radiosensitivity of pharyngeal carcinoma I am afraid that I must dissent from him entirely. The work of Berven and of Coutard fully confirms my own experience that growths in the oral pharynx, including those of the tonsil and the base of the tongue, are peculiarly sensitive to radiation and it is in these cases that the method of inserted plaques is specially applicable. The exact construction of the plaque and the arrangement of the radium within it are however, of considerable importance if good results are to be obtained.—I am, etc.,

London W.1 May 27

H. S. SOUTAR.

Influenza and Industry

SIR—The article of Dr. William Blood in your issue of May 22 (p. 1079) calls for some comment. The average incidence of fresh visits to insured persons as compared with fresh visits to their dependants is usually in the ratio of 1 to 3 or 1 to 4. At the outbreak of the recent epidemic this rose abruptly for a few days to a ratio of 2 to 1. This bears out Dr. Blood's observation that the chief cause of initial spread was through the workmen, but if reference be made to the *Journal* of October 25, 1919 an article will be found on the Spread of Influenza

in an Industrial Area," which I contributed. It was shown that of the three great waves of the 1918-19 epidemic only in the first and mildest wave did infection appear to be associated with the workshops. In the two later waves, and it was in those that most of the serious cases occurred, there was a slow spread throughout the area in which neither church, school, place of entertainment, nor workshop could have played any integral part. Infection through the workshop appears to be to the advantage of the worker. His illness is less serious than when it follows that of some other member of the household. Furthermore, as he usually comes earlier under observation than a dependant it enables the risks associated with household infection to be dealt with sooner. Since 1919 only two insured persons under my care have died from influenza, and the circumstances surrounding their deaths testified, even from the point of view of treatment, to the paramount importance of attention to the atmosphere of the sick-room and the home.

Dr Blood draws attention to the lower incidence of the epidemic among "the female members of the office staff" as compared with "the female factory hands, and expresses surprise. An explanation based on the observations of the late Sir William Hamer and given to the Royal Society of Medicine might be suggested. He divided a group of his intimate friends into vagotonics, normals, and sympatheticonics. This was based on a classification suggested by the writings of Eppinger and Hess. He found the vagotonics the most susceptible to influenza. The study of his arguments led to the belief that he had furnished a valuable clue to many of the problems of influenza. Certain of these I had indicated in the paper of 1919. He kindly afforded me the opportunity to meet some of his friends whom he had classified. It is true that in his argument he had made use of Hering's biological conceptions, which are somewhat out of date. Also the recent discovery of the dual action of the vagus in digestive processes must modify the accuracy of the terms which he had used in his classification, but there is little doubt that the clinical picture he presented is characteristic of any influenzal epidemic, and the apparently well nourished by whatever name they may be called, are the most susceptible to influenza. I write as a student of six epidemics in one area. One can hardly blame Sir William Hamer for having presented his observations under cover of complicated theories because of the surprising deductions which may be drawn from them, but it is probable that Dr Blood's observation in regard to the office girl can be explained by the modern fashion of the slim figure. The office girl pays more attention to this than the factory girl and the single girl more than the married woman—I am, etc.,

Halifax May 29

A. GARVIE.

Malaria Control

SIR—In the last epidemic of malaria in Ceylon there were 1,500,000 cases, 70,000 deaths in six months, and 30,000 lb of quinine and large quantities of atabrin and plasmoquine were used—a terrible admission of the failure of the measures adopted.

Whenever the destruction of adult mosquitos is advocated as a measure of malaria control experts immediately rise up in arms to defend anti-larval measures. The two stock arguments invariably brought forward are (1) that anti-larval control is the proved and accepted method and that it is infinitely superior to the destruction of infected mosquitos and (2) that as swarms of mosquitos are daily flying from the breeding grounds to

the houses it is impossible to destroy them all and therefore useless to destroy any.

This is precisely the same criticism that was raised in regard to the utility of anti-larval measures, but experience proved that a reduction of the number of mosquitos by larval control reduced the incidence of malaria, and it is equally certain that by reducing the numbers of mosquitos in infected houses we can effect a very great reduction in the incidence of malaria at present increased, by mosquitos which have escaped the anti-larval methods.

1 (a) No one would disagree with the great value of anti-larval measures but very few places can afford to spend the vast sums that are necessary in order to carry out these measures efficiently. In poor countries like the West Indies the effects are small and disappear when the measures cease. (b) Anti-larval measures require time and while they are getting under way swarms of anopheles mosquitos are breeding daily flying to adjacent houses, and spreading malaria. (c) During wet weather the effects of anti-larval measures are greatly diminished.

I am not suggesting that anti-larval measures should be discontinued or lessened, but I am advocating the destruction of adult mosquitos, not as an alternative but as a valuable adjunct to anti-larval measures.

2. If mosquitos are not destroyed in the houses where there are acute cases of malaria sooner or later gametocytes will appear and will infect these mosquitos. Surely that is one way in which epidemics of malaria develop and as long as swarms of mosquitos are breeding in adjacent pools and swamps the more urgent it is to destroy the adult mosquitos which are likely to become infected. Carry on the anti-larval measures in every possible way but carry on also the daily destruction of adult mosquitos as an important secondary measure.

The people can be taught to destroy adult mosquitos in their houses by swatting, fumigation and trapping. These methods of destroying them are of great value in any campaign against malaria. Public health authorities who are entrusted with the lives and health of the people living in malaria zones assume a very great responsibility when they neglect any method which will afford protection additional to that provided by anti-larval measures, especially when this could be done at such a relatively small cost—I am, etc.,

Enuresis in Children

SIR,—The article by Dr H G McGregor in the *Journal* of May 22 is of great interest. The self-help plan which I introduced into our Homes about ten years ago has been so good that belladonna bromide, etc., are used only for the very few more persistent cases.

DRY NIGHT SHEET

For the month	193	Name	Age				
	1st week	2nd week	3rd week	4th week			
Sunday							
Monday							
Tuesday							
Wednesday							
Thursday							
Friday							
Saturday							

A red star to be entered for a dry night

Above is a specimen of the "dry night sheet" used in the Homes. The object is to encourage the child to see how many red stars he can get in a week and whether he can score over the previous week—I am, etc.

Dr Barnardo's Homes E.I. May 24

A H MACDONALD
Chief Medical Officer.

SIR—It would add to the interest of Dr H G McGregors paper on this subject (*Journal* May 22, p 1061) if he would add the cases which he failed to cure, and his views of the causes—I am, etc,

London, SW 3 May 24

W S A GRIFFITH

[Dr MCGREGOR writes in reply I believe that the failures in my series of enuresis were in most instances due to my own inability to capture the child's interest in a treatment which is more in the nature of a pleasant game than anything else. The child achieves a dry night and is made much of at the next consultation, the record that he keeps merely serves to fix his dry nights as a personal achievement. Ten of my failures were obviously bored with the whole procedure, and in no way could I move them. I regard this, however, as a failure in my application of the principle and not as a failure in the principle itself. The remaining four cases, as indicated, had some physical concomitant to their enuresis, which presumably was too powerful an aetiological factor to be overcome by a purely mental attitude. Although I do not wish to leave the impression that this is the only method of treating enuresis, I do believe that in the absence of organic cause a great many cases can be relieved if they can be persuaded to take a lively interest. The method I reported is only one of many that might be used to secure it. The success of any such method depends on the individual clinician.]

Technique in Knee-joint Surgery

SIR,—Professor Graham Simpson, in your issue of May 22 (p 1088), raises some interesting points on the above subject, and criticizes my recent lecture in kindly terms. He suggests that a preparatory dressing from the toes to the groin is distinctly fussy, and that a soap and water bath from the sole to the vertex would be more rational. If the skin preparation does not extend to the groin it is impossible when scrubbed up to apply the tourniquet high, and this is very necessary for the proper application of the wool compress at the close of the operation, before the tourniquet is removed.

Professor Simpson seems to doubt both the possibility of wound infection from within and the necessity for any sort of preliminary skin preparation before operation. These are subjects which might well be debated in your columns, but which were beyond the scope of a post-graduate lecture—I am, etc,

London W 1 May 31

ERIC I LLOYD

Blood Transfusion in Obstetrics

SIR—Mr Owen Jones in his letter published in the *Journal* of May 22 (p 1090) reiterates a principle which I have emphasized for some years—namely, that when a patient is so ill as a result of haemorrhage that intravenous infusion is necessary delay is dangerous, and a stock solution should be introduced into the venous system immediately whether or not a blood transfusion will be required later.

Although I favour an ephedrine glucose gum solution for this purpose I should like to reassert that I consider the principle involved to be even more important than the actual composition of the solution provided that the latter is of a colloidal nature. My preparation proved to be the most efficacious of the several mixtures I tried out during the five years preceding 1935 and I have not since been able to improve the formula. A secondary serious fall in blood pressure following a good response to the primary infusion is seldom met with, provided that

1 The warmed fluid is introduced very slowly into a vein. I now look upon forty minutes as the minimum time for intravenous infusion of one pint of solution.

2 A liberal supply of glucose water is given by the mouth and when necessary tap water is given per rectum to supplement and maintain the fluid level in the body.

3 The introduction of fluid into the vascular system in excess of requirements is avoided during the stage of recovery of the capillary endothelium.

4 Overheating of the patient, causing excessive fluid loss by perspiration is guarded against.

5 Sedatives are administered for uneasiness or frank restlessness.

6 Inessential obstetrical manipulations and transport to hospital are postponed as recommended by Professor Claye (*Journal* May 15 p 1044) until the condition of the patient is satisfactory. Transport from the patient's home to hospital is less frequently necessary where a 'flying squad' scheme is in operation.

7 A blood transfusion is given after the simple infusion as soon as a donor can be obtained when a cataclysm of haemorrhage has been preceded by recurrent minor haemorrhages and when in addition recurrent syncope attacks, sighing respiration or slow recovery follow the primary infusion.

With regard to the method of infusion, I feel that the simpler the apparatus and technique the less likely are delays and difficulties to be encountered. For this reason I support the view put forward by Dr Malcolm Black that the gravity method is most satisfactory for routine use—I am, etc,

WM HUNTER M.D., M.C.O.G.

Newcastle upon Tyne, May 22

SIR—In his letter (May 22, p 1090) Dr R Owen Jones gives as avoidable causes of post partum haemorrhage too free use of unsuitable anaesthetics such as chloroform and, most important of all, faulty management of the third stage. He continues "It is disheartening to find so many attendants—midwives and doctors—grasping and kneading the uterus. The hand control 'ling' the uterus cannot resist that fatal reflex kneading with resultant incomplete recovery of uterine tone and irregular and unnatural separation of the placenta. Does Dr Owen Jones mean all this, or are these just words, learned-like in sound, and no doubt written with puckered brow and sternly set mouth? What is his proof, experience or statistics behind the "fatal reflex kneading" "the resultant incomplete recovery of uterine tone, and "the irregular and unnatural separation of the placenta"? It is these irritating meaningless phrases that make one fed up with so much that is written upon obstetrical subjects. I fully realize that chloroform is not loved by many obstetrical specialists. But who said that it caused post partum haemorrhage? From May 1 1915, until April 30 1936 I used it in 475 cases and I never saw it cause post partum haemorrhage. My only cases of post partum haemorrhage had no anaesthetic. I acknowledge that these are not very many cases but surely, being a headstrong Highlander I would, in at least a few cases have made 'too free use' of this unsuitable anaesthetic and Nature would have inflicted her reprisals upon my poor victims. In spite of all Departmental reports and the lectures and warnings of multitudes of my specialist friends long experience has convinced me that chloroform used in the cases which do not contraindicate it is the best of all obstetric anaesthetics for the rural physician and the chloroform capsule one of the greatest boons of modern times. I now rarely use the chloroform bottle. I manage the majority of manipulative procedures including the use of forceps without hurting my patient with the chloroform capsule alone.

Then we come to the third stage I differ entirely from Dr R Owen Jones, and regret to write that I belong to the disheartening class of doctor. My advice is to control the uterus by having your own hand, or that of the nurse, in touch with the fundus until the placenta is in the dish. Two of the worst cases of post-partum haemorrhage that I have seen were those in which the nurse left the patient to Nature, turned her back upon the bed, and proceeded to bath the baby. I arrived late, but just in time. In both cases I found the patient pulseless, the bed flooded, and the nurse in blissful ignorance with the skirling bairn in her arms. Femergin and coramine quickly put the patient right, but it might well have been otherwise had I been a few moments later. I was once caught napping myself. I hope the Central Midwives Board will not adopt Dr Owen Jones's suggestion of an hour glass, if it does he will have to run a sort of police car transfusion service in Denbighshire.

I think success in the third stage depends a great deal upon a proper management of the first two stages of labour. I was glad to note, in reading of a recent discussion at the Edinburgh Obstetrical Society, that even eminent authorities no longer hold the 'unruptured membranes' sacrosanct. Nature is often far from right, she will rupture the membranes in a breech or an occipito-posterior case when she might well leave them alone, and she leaves them whole when they are a source of delay and fatigue. In both types of case her behaviour is responsible for trouble in the third stage, but then she is Nature, and according to authority your fingers should be in your mouth and not in the vagina where they can do some good. In a normal presentation with a normal pelvis I rupture the membranes in a multipara, when the os is about three quarters dilated, or, to put it more accurately, when experience and instinct tell that the head will be a better dilator than the bag of waters. In a primipara this is done a little later, but I never delay when I feel the bag of waters are hindering the head from coming down through the os. In a multipara I give 1/2 c.c. pituitrin whenever I rupture the membranes, but in a primipara I delay this until the head is distending the perineum. Once the pituitrin is given I feed my patient with chloroform capsules. In a primipara, if the vaginal passage and the perineum are tight, before rupturing the membranes or giving pituitrin I dilate them by carefully and gently under a chloroform capsule anaesthesia inserting my hand into the vagina, closing my fist, and withdrawing it with rotatory motion. This is a useful procedure in a breech presentation also going on through the os if need be. In doing this I can, to the ultimate advantage of mother and child, put the breech in the position suggested by Dr Alec Bourne, not bringing the legs outside the os. By these procedures I have saved many perineums and rarely have trouble with the placenta. I have had to remove the latter manually in twenty-seven out of 1279 cases—that is in just over 2 per cent of cases—and I have had only five cases of post partum haemorrhage these giving practically no trouble in spite of the fact that I always guard the fundus after the birth of the child and push out the placenta once I am sure that it is in the vagina. All this may seem terrible and fill some minds with horror that it should be permitted in a civilized country, but it is a procedure which long experience has taught me to be correct. In conclusion I would again impress upon Dr Owen Jones and those like minded that it is during the first and second stages of labour and by the ante natal checking of toxæmia that a successful third stage is achieved—I am, etc.

E. K. MACLEZIE

Medicinal Kaolin in Food Poisoning

SIR,—I was interested in the letter from Dr Nathan Mutch in the *Journal* of April 24 (p. 886), and would like to suggest that if anyone considers the desirability of working out dosage tables applicable to the use of medicinal kaolin as an antidote for food poisoning he might at the same time study the comparative evaluation of activated carbon.

There is a wealth of references to this substance in recent medical literature. Its value as an adsorbent of bacterial and alkaloidal poisons has been fully established. Lucas and Henderson for instance, quote twenty-one cases of poisoning in which death would presumably have occurred and in which recovery followed the administration of charcoal. The cases cited include seven cases of phosphorus poisoning, three cases of morphine poisoning, two cases each of corrosive sublimate, chlorate of potash, and lysol poisoning, and one case each of arsenic, mercury, veronal, omnopon, and absinthine poisoning.

Strychnine poisoning is particularly well treated with activated charcoal. It is important to ensure that the charcoal used is of the activated type. There are several reliable proprietary brands of the product available, and a monograph on them is included in the current edition of the *British Pharmaceutical Codex*. H. Brindle, F.I.C., of the University of Manchester has shown that one of these activated charcoals, Chardox (E. Griffiths Hughes, Ltd.) has an adsorptive power on strychnine as follows: 30 per cent is adsorbed in one minute, 34 per cent in ten minutes, 34.5 per cent in fifteen minutes, and 36.5 per cent in thirty minutes. The first figure is of course the most important one when considering its use as an antidote. It should be borne in mind, however, that ordinary non-activated medicinal charcoal possesses only about one-fiftieth of the adsorptive capacity of Chardox.—I am, etc.,

Alderley Edge, May 27

Intra-epidermic Vaccination

SIR,—I can confirm the claims of Dr E. R. Peirce (*Journal* May 22, p. 1066) as to the advantages of intra-epidermic vaccination over the ordinary method, as I have been using it for a number of years in Burma, but we had not then learned the procedure, so well described by Dr Peirce, of economizing the lymph. There is one point which I have noticed quite often in connexion with what Dr Peirce termed the vaccinoïd reaction and that is the tendency for the vesicle to persist for as long as a fortnight before gradually drying up. I regard this as a proof of success in revaccinations.—I am, etc.,

MIN SEIN

London, W.1, May 23

Treatment of Peptic Ulcer

SIR,—Dr Sandweiss's article (*J. Amer. med. Ass.* 1937, 108, 700), referred to in an annotation in your issue of May 8, may well be taken to mark a notable advance in the approach to treatment of the general condition liable to culminate in gastric or duodenal ulcer, in the evidence he puts forward as to the purely illusory effects of alkalis, diet, vaccines, injections, or surgery, as being of lasting or curative value.

In this country too vast numbers of people who have been treated by these methods have not derived more than temporary benefit and in spite of the conviction of medical and surgical specialists who have written much

on the subject to the effect that the methods have in their hands proved satisfactory, many of their patients have not been able to share this conviction that anything in the way of permanent relief has been reached

It has thus come about that the invidious task of sorting out results commonly falls to the lot of the general practitioner, of whom there must be many who can add their testimony to the value of the observations so clearly summarized by Dr Sandweiss, and which, moreover, are so plainly reflected in the drawn, starved, soured faces of those who, sometimes for years on end, have submitted to the regime imposed. That the relief afforded by the chemical assault on natural juice is but momentary is the avowal of all. The entire frame betrays the devitalizing effects of a restricted diet based on apprehension, while the stultifying action of dope is by no means negligible. Finally, when all these measures, patiently carried out, have failed, the scar of a knife too often betokens the fact that the last hope of recovery of the victim of despair has, in his judgement, been inadvertently severed.

Now that Dr Sandweiss has made it so clear to us that it is useless, and perhaps we can now see quite irrational, to attempt to "cure" peripheral manifestations of central disturbance by local means alone, it may be judged not amiss to look at the matter from the angle of the general practitioner, who in the long run has to deal with the majority of such failures.

While it is generally recognized that the controlling centres of visceral activity are largely represented by the autonomic system, it does not appear that much attention has been paid in practice to this essential point, although disturbances in this system have proved clinically to be a dominant factor in the chronicity of such states as conduce to haematemesis or ulceration in a visceral area, and local lesions to respond to general measures even in the complete absence of any local treatment.

In submitting the general hypothesis that the most rational line of treatment of the peptic ulcer diathesis is afforded by control of central disturbances of the autonomic system, popularly referred to as 'emotional,' there is ample clinical evidence to support the view that, provided that a patient is sufficiently well orientated to exercise his own volition in maintaining control of his feelings either with or without the subsidiary aids commonly made use of to lessen peripheral disturbance, permanent cure may be looked for with confidence in every patient of stable character. It stands to reason that both the patient's and his medical advisers' difficulties are in no way lessened when the former has become excessively body conscious through insistence that his gastro-duodenal failure is still primarily at fault, and particularly when volition has been impaired by morphine—I am etc.,

May 27

Reform of the Medical Curriculum

SIR.—A hopeful sign for the progress of the movement for reform of medical education in this and other countries is the interest in the subject revealed by the instructive letter in your issue of May 29 from Professor G A Clark, Dean of the Faculty of Medicine of Sheffield University. From his reference to the present Edinburgh movement I venture to suggest that Professor Clark is under a grave misconception as to the real issues. He states that as a result of the far-seeing enlightened policy adopted by the Sheffield Medical School no adjustment is necessary to satisfy the new requirements of the General Medical Council. That may quite well be, but the real crux of the Edinburgh movement was the recognition of the fact that the 'requirements' of the GMC and its power to see them effectively in operation are not in keeping with present-day needs.

Professor Clark's letter recalls to my mind two facts which I think have some relevance in answer. In the course of a recent discussion on the reform of medical education at the Society of Medical Officers of Health in London, Professor Picken referred to the answer commonly given by university and other teachers to the charge that the teaching of preventive medicine using that term in its widest sense, is too systematically overlooked—namely, 'We are doing that already.' In the opinion of the increasing body of reformers this answer has little relation to facts. Again, over two years ago I got a letter from a well known medical teacher in a university informing me that its curriculum had just been fully revised a satisfactory feature being the rapidity and ease with which the necessary changes had been amicably arranged. A few months ago the new Principal of the said university publicly condemned the present system of medical education as the worst system that had ever been devised, consisting largely of a peculiarly costly kind of cramming.

The question of priority in discovery is of no real importance or value. But if it is to be raised, the analogy of the pioneer Vikings led by Christopher Columbus now smiling indulgently in Valhalla over a recent Edinburgh discovery should advantageously be replaced by one in which Hippocrates and other great masters of the past are sitting chuckling over the fact that the value of much of the neglected teaching of the past masters is now slowly being recognized—I am, etc.,

Drem May 29

CHALMERS WATSON M.D.

Maternity Services

SIR.—The British Medical Association's preference for a national maternity service as distinct from what is termed 'variable local arrangements built up more or less haphazard at the option of local authorities' (Supplement May 8 p 271) is not shared by some of us who also have given thought to the subject. My own views were stated two years ago in these words:

If my observation is correct I would not expect a powerful nor prolonged protest if it was considered desirable that the midwifery of a city should be organized and placed in the hands of men who are generally recognized as keen and competent obstetricians. Such a panel would be responsible to a central authority would undertake all institutional work and I would assume a relationship to the private patient similar to that now occupied by the operating surgeon. Such well-ordered and co-ordinated service would demand a high level of individual skill a deep sense of personal responsibility and for the patient a very thorough supervision.

Furthermore there would be available in a few years a mass of valuable clinical data which would guide the future.

policy and perfect the existing machinery of such a service in any given locality, for this at least is apparent that the solution of the problem of maternal morbidity and mortality in the black areas is not necessarily to be sought and may not be found in methods which may be applied successfully outside these areas, but will result from keen observation and an intelligent perception of economic industrial social and any other factors which have a direct or potential bearing on the issue in its local interpretation

It is with some satisfaction that I now detect a movement in official quarters towards such a service—I am, etc.,

Bradford May 25

W SUTHERLAND, M D

Good Milk and Fresh Vegetables

SIR,—It is a serious reflection on Great Britain that the death rate among Maltese children should be the highest in Europe. A high death rate of this sort is now recognized as due to defects of feeding caused by an insufficiency of good milk and fresh vegetables. The milk of Malta is obtained from goats fed on imported foodstuffs because the soil on the island is not capable of producing an adequate supply of fresh green foodstuffs, either for animals or for human beings.

Children need good lime-containing milk from healthy animals fed on fresh green foodstuffs. Can these foodstuffs be produced on the island? If not, why not? Children themselves also need fresh vegetable foods containing vitamin B if they are to grow up strong and healthy. Without good milk and vegetables the children develop poor teeth and so cannot bite, indigestion sets in and vitality becomes lowered so as to allow of the development of respiratory and circulatory diseases. I expect children if they grow up, become men and women whose physical and mental capacity is of reduced national value.

In Great Britain the national committee set up to deal with food and nutrition has emphasized the importance of fresh green vegetable food but without suggesting any special quantity. I have suggested 1 lb per head weekly, which necessitates an annual production of 950,000 tons. At present we produce only 210,000—a deficiency of 740,000 tons annually. Sir John Orr, in a recent broadcast, suggested half a pound more than I did—namely, 1½ lb per head weekly. In this case the national deficiency would be about 1,200,000 tons a year.

If my facts are of value there is something radically wrong with our food production. Farmers and gardeners are able to produce the needed amount but the distribution is at fault. Does this mean that our only hope of national salvation depends on the setting up of a national method of distribution? The question has to be faced and thoroughly discussed and medical men can make a valuable contribution both to the discussion and to the solution of the problem—I am, etc.,

Swansea May 31

G ARBOUR STEPHENS

Air Raid Precautions

SIR,—The letter of Dr Levy in your issue of May 22 (p. 1071) draws attention to a problem which is already engaging medical men. Are we to assist the Government in its endeavour to make the public air raid conscious or are we not? My own mind is made up. I believe that all attempted precautions against bombing are futile and I refuse to take part in them. Even did I believe them to be worth while there would still be the greater objection that air drill accustoms the mind to the idea that war is inevitable, whereas I believe that

the time has come when organized mass murder should be unthinkable. Coué's favourite axiom that when the will and the imagination are in conflict the imagination always wins is a psychological truth. Whether the idea which occupies the mind is a hope or a fear makes no difference there is an irresistible trend towards its realization, just as a man learning to ride a bicycle steers straight into an obstacle he is trying to avoid.

The historian of the future will be aghast at the complacency with which this generation accepts the idea that mass murder can be deliberately resorted to under any circumstances. The real tragedy of Guernica is that it is the logical outcome of the road which we ourselves have elected to travel every country which possesses bombing aeroplanes must accept a share of the responsibility.

The arguments for or against pacifism are not to the point—which is that war with its pomp and pageantry and heroic virtues has gone for ever, and that its place has been taken by inhuman mechanical and chemical mass murder which can find no advocate in any sane man. Few people in a responsible position have a full realization of this. Most of them still talk of war in language appropriate to the Middle Ages. The martyrdom of Guernica will not have been in vain if through it the world can learn this lesson—I am, etc.,

Birmingham May 28

R MACDONALD LADELL

Birching of Children

SIR,—In the present correspondence on judicial birching I consider one point has been largely overlooked. The punishment meted out to an offender is designed not only (or even mainly) to cure him of his evil proclivities, but also to act as a deterrent to others who might otherwise commit the offence. I submit that the fear of a birching does act as a deterrent.

I should be interested to know if Dr W N Maple (May 22 p. 1093) concludes from the last paragraph of his letter that the English nation is more sadistic than most Continental nations—I am, etc.,

Probus Cornwall May 22

E H EASTCOTT

SIR,—The idea that physical violence can never be justified in attempting to correct human behaviour, apart from self-defence, will undoubtedly grow, but only in proportion to the extent that the task of tracing the origin of the kinks which lead to anti-social behaviour is undertaken. The conviction that such means are justified is itself a mental kink, and is itself anti-social.

The proof lies within one's own mind, that is the difficulty, and many are unable to realize this. Complete recognition and realization of such mental kinks as normal primitive states only abnormal when unsuppressed and unrealized in adult civilized man as being part of our own nature are impossible for many alone and unaided. The proof of whether whipping cures the young of let us say, stealing or lying at some particular time and in particular surroundings is beside the point, whipping without doubt does deter many, others it does not. But what else does it do? What other effects does it produce, immediate and remote? Very different conclusions can be drawn from homely psychological lessons by different observers.

In my opinion a knowledge of latent sadism cannot be acquired from a dictionary, this is unfortunate nor can it be recognized, still less realized from such perusals. It is innate in every human soul and its grades are legion. No one likes to be told that a belief in physical violence as a proper corrective for what he believes to be childish

crimes is due to primitive and unrealized wishes, he naturally demands proof, and expects those who tell him this to produce it in the form and manner of material problems. That is not possible, hence the accusation of dogmatism.

Although surprised to see so few psychologists taking part in this discussion, I think it is probably because of the extreme difficulty, perhaps futility, of trying to convince intelligences otherwise informed by means of public letters. Nevertheless I believe it to be important and well worthy of the experienced and eminent Psychologists are aware of the far-reaching importance of this matter, indeed, it is difficult to over-estimate it. The control of sadistic impulses by their realization in all teachers, legislators, and doctors alone would go far to raise the standard of civilization—I am, etc.,

London, W 9, May 29

Herpes Zoster and Varicella

SIR,—The following case may be of some interest. A man aged 55 consulted me on account of spots on his body. He presented a typical herpes zoster of the right shoulder region extending over the deltoid, and in addition well marked chicken pox vesicles on scalp, face, chest, and abdomen. He said that between two and three weeks previously he had had a stiff neck and slight aching pain in his right shoulder. Four days before he had noticed clumps of blisters over the right shoulder, and three days later spots appeared all over him. His temperature was 99.4° F and his pulse rate 85. There had been no contact with chicken-pox or shingles. He had not had chicken-pox as a child.—I am, etc.,

London W 14, May 6

W BLOOD

Obituary

ALFRED ADLER, M.D.

Dr Alfred Adler collapsed and died in Union Street, Aberdeen, on May 28. He was in this country on a lecture tour, and had nearly completed a series of lectures on psychopathology at Aberdeen University. Dr Adler, who was 67 years of age, studied medicine at Vienna University and graduated M.D. in 1895. For thirty years he was a general practitioner in Vienna, and in 1927 went as lecturer in psychology to Columbia University, New York. In 1932 he was appointed professor of medical psychology in the Long Island College of Medicine. During his early days of practice Adler joined a discussion group of young medical men whose centre was Sigmund Freud, but twenty five years ago he deliberately broke away from Freud's influence. He was founder and president of the International Society of Individual Psychology and editor of its journal.

Sir Walter Langdon Brown writes

Alfred Adler's influence on medical psychology has been far-reaching. The deliberately challenging methods of Freud excited hostility at first and the spiritual value of Jung's philosophy is still but dimly comprehended but when Adler linked psychoneuroses with organ inferiority he enabled orthodox medicine to join hands amicably with

the new psychology. True this doctrine subsequently retreated into the background of his teaching but the bridge had been built. His theories were practical and simple perhaps sometimes too simple for the complexity of the subject, but they did demonstrate how much psychoneurotic suffering could be alleviated by the general practitioner who would open his mind to this new point of view. Obsessional and compulsion neuroses require prolonged handling by the specialist, but a vast mass of suffering must go unrelieved if such handling is the only way in simpler cases. He showed how much can be done by sympathetic inquiry into and explanation of the origin of a patient's difficulties. "You don't talk psychology, Dr Adler," once said an academic psychologist to him; you only talk common sense. To which Adler replied "Well, why do you not also talk common sense?" The early formation of the style of life, the significance of each child's position in the family hierarchy, the importance of knowing the goal towards which the individual is consciously or unconsciously striving, the vital necessity of co-operation with others—these were the main theses which, like Luther, he insistently hammered on to the door of orthodoxy. He expressed to me more than once his regret that his phrase 'inferiority complex' which is used in season and out of season, had been misunderstood. We all have or should have a feeling of inferiority, for only so is improvement possible, the term complex is only applicable when the individual allows that feeling to assume non-social, non-co-operative expression, by which he evades the responsibilities of life.

His influence in this country is seen in the rapid growth of the Medical Society of Individual Psychology, which from small beginnings was nursed by the energy and skilful, if sometimes special, pleading of the late Dr F. G. Crookshank into a sturdy adolescence. It now has 127 members, largely general practitioners, as well as a number of medical students as associates, and publishes a series of *Bulletins* which have attracted a good deal of attention. At this grown up stage it has, as adults are prone to do, ceased to confine itself entirely to the parental point of view, though abundantly honouring the parent.

Einstein once said that Adler was Sancho Panza to Freud's Don Quixote. We may allow that the simplicity of his theories was the reflexion of his personality. Unaffected by adulation, undeterred by opposition, he went serenely on his way. At the end of a strenuous week his hostess said "You must be very tired, Dr Adler." He replied "Not at all, only complications are tiring and life is so simple when you understand it."

The death occurred on May 5 at Guy's Hospital of Dr FREDERICK SANGER of Tanworth in Arden, Warwickshire. He was born in London in 1876 and from Wellington College proceeded to St John's College, Cambridge to study medicine. He took the M.A. in 1897, and went on to St Bartholomew's Hospital, obtaining the Conjoint qualification in 1899, the D.P.H. in 1902 and the M.D. in 1905. For his M.D. thesis he did original work on blood stains which laid the foundation of the modern study of blood stains in criminal investigations. He served as house-surgeon to both Addenbrookes and the Metropolitan Hospitals, and then went to China with the C.M.S. joining its mission at the St. Luke's Hospital at Hinghai in Fukien. There he remained for six years. During his life in China his wide interests brought him into touch with all classes of the community. His especial interest in education caused him to found a Chinese boys' school, pupils of which have since become eminent in modern China. Sanger was a distinguished Chinese scholar and was one of the small band of medical linguists who

the editorship of Mr. Cormack produced the first Chinese translation of Rose and Carless's *Surgery*. He returned to Europe owing to ill health, and after a two years stay in Davos he took up general practice in England. He practised at Rendcombe in Gloucestershire from 1911 to 1922, and then settled at Tanworth-in-Arden in Warwickshire, where he remained in practice until his recent illness. He acted as police surgeon, district M.O.H. to the public assistance authority, and public vaccinator. Besides running a busy rural practice Sanger found time to devote himself to many outside interests, especially in religious and educational work with the Society of Friends in and around Birmingham. He was a keen naturalist and an omnivorous reader, and was always abreast of all modern scientific and medical thought. Though never able from his rural position to take an active part in the British Medical Association (he was a member of the Birmingham Central Division) he was always a loyal member, and was very keen that all general practitioners should support the formation of the public medical services. He was particularly happy when the advent of the East Worcestershire P.M.S. enabled him to merge his club practice into that organization. He is survived by a widow, two sons and a daughter.

We regret to announce the death of Dr. GEORGE EVERARD DODSON from typhus fever on May 9 at Kerman, Iran. Dr. Dodson was a much beloved and honoured missionary of the Church Missionary Society, in charge of its hospital in Kerman. He was born in 1872 at Higher Crumpsall, Manchester, and educated at Giggleswick Grammar School and St. Bartholomew's Hospital where he qualified M.R.C.S. and L.R.C.P. in 1897. He took the further diploma of D.T.M. & H. at Cambridge in 1913. He was extern midwifery assistant at St. Bartholomew's and assistant in the orthopaedic department in 1897, gaining in both departments experience which he turned to the highest use in after-years in social service for Iran. He also held resident posts at the Norfolk and Norwich Hospital, the Royal United Hospital Bath and the Nottingham Infirmary, and he was a temporary captain R.A.M.C. during the war being appointed surgeon specialist to the Colaba War Hospital, Bombay. Dr. Dodson married Miss Emmie Lucy Wells, a trained nurse and was accepted by the C.M.S. for service in Persia (Iran) in 1903. "J.H.C." writes: During his thirty-four years of service under the C.M.S. Dr. Dodson did a work for Iran which will never be forgotten. He was a gifted surgeon, and laid the foundation of a social service and welfare work in Iran—especially at Kerman—which has been of inestimable value to that country. Two outstanding features of his professional career were his orthopaedic work among the crippled carpet weavers and his skilful obstetrical and gynaecological work which has saved the lives of large numbers of dwarfed cripple mothers in that industry. No less important was the preventive and welfare work which he instituted and which led to legislative reforms that have gone far towards revolutionizing the conditions of the carpet industry in the cities of Iran. As a missionary he was honoured and beloved for his high sense of duty and his lovable personality and his unsparring self-sacrifice in the interests of the sick and suffering. To his patients his colleagues and the many Persian friends who loved him his loss seems irreparable. He died—as he would have wished—among the people whom he had served.

The death took place at a nursing home in Edinburgh on May 13 of Dr. JAMES MILL who for many years was a well known practitioner in Leith. He was born in Leith, the son of the Rev. James S. Mill minister of Kirkgate Church in that town. He studied medicine at Edinburgh graduating M.B., Ch.B. in 1881, and joined the Royal College of Physicians of Edinburgh ten years later as a Member, being elected a Fellow in 1893. Soon after

graduation he settled in Leith where he required a large practice and was greatly respected and beloved by his patients during half a century of active work. He was an ardent volunteer and afterwards held the rank of lieutenant colonel in the R.A.M.C. Territorial Force. Early in the war he accompanied the 7th Leith Battalion of the Royal Scots to Gallipoli. This battalion, on leaving with the Expeditionary Force, had a tragic experience when one of the trains carrying the men met with a railway disaster at Gretna nearly half of the battalion being killed or rendered unfit for service. Lieut.-Colonel Mill fortunately was in the second train and proceeding to Gallipoli he rendered valuable service there. On his return to this country he was placed in charge of Maryhill Military Hospital, Glasgow, where he also did excellent work. He retired from practice some time ago after thirty-two years' membership of the British Medical Association. The funeral service at the Edinburgh Crematorium on May 15 was attended by many former patients and members of the medical profession in Edinburgh.

We announce with regret the death at the age of 74, at his home in Hertfordshire, of HENRY WILLIAM BROOKS SAVILL. Dr. Saville, who studied medicine at Owens College, Manchester, took the L.R.C.P. and the L.M. in 1891 and the M.R.C.S. Eng. some four years later. Soon after qualifying he joined his brother who was in general practice in Radcliffe, Lancashire for a few years before setting up his own practice in the same town. He was appointed honorary consulting surgeon at the Bury Infirmary, and was chairman of the Bury Division of the British Medical Association for the year 1922-3. He had been a member of the Association for over forty-five years. In his forty years of general practice in Radcliffe, Dr. Saville won the affection and respect of his colleagues and his many patients. A presentation was made to him on his retirement from active practice about eight years ago when he left the town in which he had worked for so long and settled in Rickmansworth.

The death is announced of Dr. RICHARD HENRY READ of Hanley, Staffordshire at the age of 72. A student of Owens College, Manchester, he obtained the M.R.C.S. and L.R.C.P. diplomas in 1890 and settled down in general practice at Hanley where he held several public appointments, including those of district medical officer, medical officer to the Post Office, and county surgeon to the St. John Ambulance Brigade. Dr. Read was well known as an ornithologist and had been vice president of the North Staffordshire Field Naturalists Club and Archaeological Society, and he wrote in 1894 a book on *The Nature Distribution and Uses of the Colours of Birds*. He joined the British Medical Association in 1895.

The death of Sir ERNEST MORRIS C.B.E. removes a man who did fine work for the London Hospital and its medical college. In the words of a writer in the *Times* he was the last survivor of the great triumvirate to which the hospital world must remain eternally indebted. Lord Knutsford, Miss Eva Luckes and Ernest Morris are names to be remembered with admiration and gratitude wherever hospital work is done. Ernest William Morris was appointed house governor of the London Hospital in 1903 and resigned in 1930 on reaching the age of 65. In recognition of his services he was elected a member of the House Committee and in 1932 he received the honour of knighthood. We may recall here that in April, 1919, the Council of the British Medical Association appointed a small committee to consider and report on the existing arrangements under which the work of the Association in the head office was carried on with a view to possible rearrangement and improvement, with power to co-opt a business expert to advise. Mr. Morris willingly accepted service on this committee and took an active part in its inquiry.

BOURNEMOUTH TYPHOID OUTBREAK

OFFICIAL REPORT

The report of the late Dr W. Vernon Shaw, a medical officer of the Ministry of Health, on his investigations into the outbreak of enteric fever which occurred in Bournemouth, Poole, and Christchurch in August and September last, was published on Wednesday by H.M. Stationery Office, price 9d.

The outbreak was first brought to the notice of the Ministry on August 21, 1936, and Dr Shaw began his investigations on the following day. On arrival he was informed that thirty cases of enteric fever had been notified during the preceding twenty-four hours, and that medical practitioners in Bournemouth and Poole reported that they had a very large number of other patients, who would probably prove to have enteric fever, under observation. The patients were scattered throughout the three towns without distinction of age, sex, occupation, or social status, and it was clear that a widely distributed article of food or drink was concerned in the spread of the infection.

Raw Milk Inculpated

Dr Shaw ascertained that the only factor common to all the patients was the consumption of raw milk retailed by one distributor. This distributor, acting on Dr Shaw's advice, adopted a form of commercial pasteurization (heating the milk to 160° F.) for the whole of his supply, and distributed no unpasteurized milk after the morning round on August 22. This measure was immediately successful in terminating the outbreak. Dr Shaw concluded that the milk was infective for a period of about thirty-one days preceding August 22, and that the approximate number of persons who had contracted the disease was 718, of whom 518 were residents and 200 visitors. The deaths of residents numbered fifty-one.

A Contaminated Stream

No source of infection could be discovered among the personnel employed in the distribution of the milk or at the retailer's depot, and investigations were accordingly made at the farms from which the milk was supplied. The supply was collected from thirty-seven farms scattered throughout a large part of Dorset; all were visited and inquiries made into the health of such of the personnel as had had any part in the production of milk during the critical period. In all 192 persons were examined, and two at one farm were found to be suffering from enteric fever. They were the wife and son, aged 12, of one of the milk producers. A careful examination of the circumstances in which these persons became ill led Dr Shaw to conclude that neither was the cause of the outbreak, though there was strong presumptive evidence that the milk produced at the premises in question was the source of infection of the retailer's supply and of the farmer's wife. Dr Shaw also ascertained that in the house adjoining that occupied by the farmer a fatal case of enteric fever had occurred in May 1934 when the water supply of the two houses—which was common also to eight other houses in the vicinity—was suspect. It was derived from a well 162 feet deep situated 100 yards from a small stream which ran within a few yards of the two houses. Repeated examination of the well water proved that it was liable to pollution, though at times it yielded a good potable water. The condition of the stream was investigated and into it at a point about half a mile up stream from the farm the sewage effluent from a house in the neighbourhood was found to be discharging. Bacteriological examinations of the effluent for the presence of the typhoid organism proved negative on four occasions in September and early October, but it was found to be present in large numbers on two further examinations in the latter part of October. The occupants of the house were examined and one of them, who had been living

there in April, 1934, and in July and October 1937—that is, during the material periods—was found to be harbouring typhoid bacilli in his digestive tract and excreting them. The person in question was unaware that he was a potential source of danger to others, and he complied at once with the suggestions made to eliminate any further contamination of the stream.

Practical Conclusion

Dr Shaw was satisfied that the outbreak was due to the consumption of raw milk, and that the dealer's supply was infected by the contributions of one or possibly two producers whose milk in turn was infected by the contaminated water of the stream. How the infection was conveyed from the stream to the milk, whether by the use of the water or of a certain well, or by the cows subsequent to their drinking at the stream, was not determined. The suggestion that a cow may excrete typhoid organisms in her dung or even in her milk is apparently a novel one, but one which Dr Shaw found himself unable to reject.

The Chief Medical Officer of the Ministry, Sir Arthur MacNalty, in a prefatory note submitting the report to the Minister, draws attention to the fact that the bulk supply of milk was infected by a relatively small contribution itself produced without apparent fault. He concludes that 'in the present state of our knowledge where large milk supplies and commensurate risk are involved the only practical way to reduce the risk of such outbreaks to a minimum is by pasteurization'.

Medico-Legal

A FATALITY AFTER DIPHTHERIA IMMUNIZATION

The consulting physician to Ring Irish College Co. Waterford, Dr Daniel T. McCarthy, advised the authorities of the college last September to have their pupils immunized against diphtheria. He procured from the county medical officer of health a supply of T.A.F. (Burroughs Wellcome) for which the makers claim a high immunizing effect with a very low tendency to cause reaction. On November 9, 17, and 24, 1936, he gave intramuscular injections of 1 ccm. each to thirty-eight children at the college. The preparation was supplied in rubber-capped bottles each holding 25 ccm., and the doses were withdrawn in the ordinary way by puncturing the rubber cap with the needle of the syringe. Early in January the mother of one of the children, a girl of 12½ named Siobhain Kenneally, consulted Dr McCarthy and informed him that the child had a sore arm, which had developed during the Christmas holidays. On examination he found at the site of injection, which was just above the level of insertion of the right deltoid, a small discharging circular ulcer about 3/8 in. in diameter. The axillary glands were enlarged and tender and the child appeared to be in poor general health, anaemic and debilitated. He prescribed for her general health and for the treatment of the local condition. In April he was called in again and found the child much worse. He consulted other practitioners and the county pathologist, Dr W. J. O'Donovan, made bacteriological examinations. Clinically she appeared to be suffering from acute thrombocytopenic purpura. On April 19 she received a blood transfusion but she died the next day. Forty-four children who were immunized about the same time at another college from the contents of the same lot of ten bottles suffered no untoward results.

The Coroner's Inquest

Dr McCarthy duly reported the death and the inquest was begun on April 21 and continued on May 19 and 21. It was held by Dr WALSH, coroner for East Waterford.

Dr O'DONOVAN who had conducted the necropsy, said that the child had died from toxæmia and purpuric hæmorrhage consequent on general infection by miliary tuberculosis. Three days before death the blood showed a purpuric condition. After death he found numerous petechial hæmorrhages in various parts of the body, a chronic lacerated lesion on the outer aspect of the right arm, and a palpable mass in the right armpit. The lungs did not collapse, were of grey appearance, and were studded with minute tubercles. There were groups of tubercles in the lining of the chest cavity on both sides of the apical regions. There were small hard tubercles on the liver surface and the liver was slightly enlarged, the spleen was enlarged and studded with tubercles on its surface and throughout its substance. There were hæmorrhages in the stomach wall and blood throughout the intestines. There was hæmorrhage in the pelvis of both kidneys and into the tissues of the floor of the abdomen on both sides. There were hæmorrhages into the scalp tissues and dura mater. There was no evidence of meningitis, tubercles were not seen in or on the brain surface and the mesenteric glands were enlarged. The right axilla contained a mass of enlarged glands with hæmorrhagic softening, and on microscopical examination tubercle bacilli were demonstrated in lung liver spleen kidney, and glands, and in one small nodule that was removed from the brain. The tissue from the ulcerated lesion on the right arm was a chronic inflammatory process which could not definitely be diagnosed as tuberculous and in which tubercle bacilli were not found, but its appearance was consistent with tuberculous ulcer. The acute condition was of perhaps a few weeks standing. There was no evidence of chronic tuberculosis.

Dr O'Donovan said he had never heard of a case in which the subcutaneous inoculation of tubercle bacilli had caused any form of tuberculosis infection. In this case, he said, the disease had been caused by a tuberculous ulcer and disseminated throughout the body, leading to purpuric hæmorrhage. A connexion between the inoculation and the generalized infection was possible. The condition could not have been caused by anti-diphtheritic immunization properly administered. There were no signs on the body of old tuberculous lesions. The condition would be a possible result of "living tuberculous serum."

Dr MCCARTHY described the inoculations and the course of the case, and added that all the syringes had been sterilized in an electric sterilizer and sent to the school in a sterilized drum. Every usual precaution had been taken. He had been dealing with no cases of tuberculosis either in hospital or in private, and had no preparation of tuberculous material in his possession. He could not recollect whether this child was the first to be inoculated, but she had been among the first. He had known of no case of tuberculosis in the college during the last few years. The county medical officer had kept the bottles in sealed boxes in his office and Dr McCarthy had fetched them himself.

A Bacteriologist's Evidence

Dr J W BIGGER, professor of bacteriology, Trinity College Dublin, said that he had inspected the research laboratories of the Wellcome Foundation, Ltd., of Langley Court, Beckenham, Kent, where the T.A.F. had been manufactured. He had been given every facility for investigation. He had followed the various stages in the preparation of T.A.F. and inspected all the original records dealing with the two batches from which the flasks had come. At every point in the manufacture the freedom from contamination was tested microscopically, culturally, and by animal inoculation. The tests were more complete and more numerous than were required under the Therapeutic Substances Act. He had devoted particular attention to the three departments where cultures of tubercle bacilli were kept, and found them quite separate

from the departments in which T.A.F. was bottled. The staffs were completely distinct and each was unfamiliar with the work of the other department. He was satisfied from his inspection that no addition of tubercle bacilli could have been made to a bottle of T.A.F. He had particularly investigated the possibility of substitution, and had found no sufficient motive to impel anyone to make it. An attempt, moreover, would be faced with unsurmountable difficulty. To make a suspension of tubercle bacilli even remotely resembling T.A.F. would require expert bacteriological knowledge and even he himself would find it difficult. In addition to expertness in filling, capping, tying, labelling etc., a detailed knowledge of Langley Court laboratories and of the various cultures and store places would be needed. To effect a substitution the collaboration of at least two persons in quite different departments would be required. Professor Bigger's final conclusion was that neither by accident nor by deliberate design could any preparations issued from the Wellcome laboratories and labelled T.A.F. contain living tubercle bacilli. He had tested samples taken from the batches from which the Ring College bottles had come and had found them sterile. Infection was not possible at the laboratories. He had recently inoculated forty students with the same material.

Dr H J PARISH, head of the bacteriological department of the Wellcome Laboratory, described the preparation of T.A.F. The first intimation of trouble had been a personal letter sent on February 23, 1937, by Dr Saunders to the director of the Wellcome Physiological Research Laboratories, saying that about eighteen children had sore arms and that the condition was thought to be tuberculous. After further correspondence Dr Parish had gone to Ireland and seen Dr O'Farrell, Dr McCarthy, and Dr Saunders. The records of both batches of serum showed that they had passed all tests on repeated occasions and on single bottles after having been filled. The coroner adjourned the further hearing for advice as to his jurisdiction, for he was taking the place of Dr McCarthy and his deputy, who were both concerned in the case.

Comment on this extraordinary case would therefore not be proper yet. It seems incredible from the medical evidence already summarized (for a report of which we are indebted to the *Cork Examiner* of May 20 and 22) and from the reputation of the manufacturers that this preparation could have been contaminated when it left the laboratory.

Universities and Colleges

UNIVERSITY OF OXFORD

At a Congregation to be held on Tuesday, June 8 the following business will be presented to the House. That any medical student of a university in Great Britain or in Northern Ireland or the British Dominions or Colonies may be admitted to the status and privileges of a senior student provided that the university shall have been approved by the Hebdomadal Council and that he shall have pursued at that university, or should the Hebdomadal Council in his case so approve at more than one university for at least three years a course of study leading to a degree in medicine and shall have passed all examinations incidental to that portion of the course.

It is hoped to make an election to a lectureship in physiology at Brasenose College on the foundation of William Hulme towards the end of the present year. The lectureship will be tenable in the first instance for three years and at the end of that period may be renewed for a further period of two years. The initial stipend will be £350 per annum with annual increments of £25 and the lecturer will be entitled to partake of the common college dinner without charge and will be given the privileges of common room. The duties of the lecturer will be to undertake research in some branch of medical science and to exercise general supervision over

members of the college studying medicine for the honour school of physiology and the First B.M. and to give them instruction in physiology. The lectureship may be held concurrently with a demonstratorship in one of the university laboratories but the lecturer will not be allowed to undertake other teaching work without the consent of the college. The lecturer will be expected to enter on his duties at the beginning of next Michaelmas term. Preference will be given to candidates who hold a medical qualification and to graduates of Oxford University. The choice of the electors will not necessarily be confined to those who apply. Applications accompanied by references and not more than three testimonials should reach the Principal of Brasenose by June 26.

UNIVERSITY OF CAMBRIDGE

At a congregation held on May 29 the following medical degrees were conferred

M.D.—J. B. Harman
M.B.—B. CHIR.—W. J. E. Phillips, J. W. Hannay, G. F. Wright
T. E. S. Lloyd, J. W. Crofton
M.B.—F. R. Berridge *F. Braithwaite, K. O. Black, T. C. Gipson, T. L. H. Shore, A. R. Kelsall, F. G. Booker, L. J. Pailing, J. Woodrow, A. C. L. Houlton, C. R. McLaughlin,
R. H. A. Swain, W. F. Walton
B. CHIR.—*T. M. Daniel

* By proxy

UNIVERSITY OF LONDON

At a meeting of the Senate held on May 19 the Ph.D. in Medical Vital Statistics (non-clinical) was awarded to E. Lewis-Fanning (London School of Hygiene and Tropical Medicine).

UNIVERSITY OF DURHAM

At a special convocation in connexion with the centenary of Durham University to be held on July 1 and 2 the degree of D.C.L. will be conferred on Sir Cuthbert Wallace, Bt, K.C.M.G. President of the Royal College of Surgeons of England.

UNIVERSITY OF LEEDS

The University Court has resolved to confer on July 5 the honorary degree of LL.D. upon Professor John Kay Jamieson, M.B. Ch.B., professor of human anatomy and embryology in Trinity College, Dublin, and formerly dean of the faculty of medicine and professor of anatomy in the University of Leeds.

UNIVERSITY OF MANCHESTER

Dr J. G. Woolham has been appointed honorary assistant lecturer in physiology.

Medical Notes in Parliament

In the House of Lords on June 1 the Exportation of Horses Bill, the Marriage Bill, and the Statutory Salaries Bill were brought up from the Commons and read a first time.

Tributes to Sir Stanley Baldwin on his retirement from the Premiership were spoken in the House of Commons on May 31 and in the House of Lords on June 1. In the Commons allusion was also made to the retirement of Mr Ramsay MacDonald from the Government and to the fact that he remains a Member for the Scottish Universities.

Mr Neville Chamberlain, the new Prime Minister, spoke in the House of Commons on the Finance Bill on June 1. He announced that the National Defence Contribution would not be proceeded with and that the Chancellor of the Exchequer, Sir John Simon, would substitute proposals for a simpler tax on the profits of industry.

In the Ministerial changes which followed the acceptance of the Premiership by Mr Chamberlain, Mr R. H. Bernal succeeded Mr P. S. Hudson as Parliamentary Secretary to the Ministry of Health. Sir Kingsley Wood remains Minister of that Department.

In the House of Commons on June 1 the Hydrogen Cyanide (Fumigation) Bill which had passed the House of Lords was read a first time. The Civil List Bill was read in the House a third time.

Factories Bill in Committee

The Factories Bill was further discussed by a Standing Committee of the House of Commons on May 25. On Clause 144 (Interpretation of expression factory) Colonel SANDEMAN ALLEN moved to exempt from the Bill a shop as defined by the Shops Act. Mr RHYS DAVIES said that a great number of large shops had premises inside which were to all intents and purposes factories. Mr GEOFFREY LLOYD agreed that there were attached to some shops veritable small factories; it might be dressmaking establishments or in butcher shops where sausage-making machinery operated. It would be unwise to withdraw the protection of the safety provisions of the Bill from those who operated power-driven sewing machines or sausage-making machines. The amendment was withdrawn.

Mr SHORT moved to include premises where switching operations were performed. Mr LLOYD said switching stations in certain circumstances might be as dangerous as converter transformer and generating stations but the number of accidents in switching stations was not large. The Electricity Commissioners lately issued a new code of regulations which included an additional regulation for the safety of employees engaged on operations which did not come within the scope of the Home Office Electricity Regulations. If that regulation did not meet the point raised by Mr Short the Home Office would consult the Electricity Commissioners to see whether further provision could be made. Mr Short withdrew his amendment. An amendment was made on a motion by Mr LLOYD leaving the courts to decide the line of demarcation between the Factory Acts and the Safety in Mines and Quarries Acts in the case of surface works connected with mines and quarries. Clause 144 as amended was then approved.

On Clause 145 (General interpretation) Mr BANFIELD moved an amendment to make the definition of confectionery more clear and to cover the baking of tea bread and scones. He said it was undesirable that foodstuffs should be made at places where no supervision was possible. Mr LLOYD said this matter depended on the result of the inquiry in progress into night baking. He could not say when the report of that inquiry would be published. Mr Banfield withdrew his amendment.

Sir JOHN SIMON moved amendments affecting the definition of 'young person'. He said that although the Bill spoke of persons who had attained the age of 14, the attainment of that age was not to the point unless the young person was one in whose case the new Education Act permitted that he should be released before the age of 15 for beneficial work. It was not true that every child of 14 could be legally employed in a factory. The amendments proposed by Sir John were accepted as also was a similar one in respect of Scotland.

The title of the Bill was approved and the Committee adjourned.

WORKING HOURS OF JUVENILES

Consideration of the Bill was completed on May 27, when new clauses were taken. In fulfilment of a pledge given at an earlier sitting, Sir JOHN SIMON moved the new clause entitled "Reduction of weekly hours of work of young persons under 16" which provides as follows:

"Subject to the provisions of this section as from the expiration of a period of two years after the commencement of this Act, the foregoing provision of this part of this Act limiting the hours worked in any week exclusive of intervals allowed for meals and rest, shall have effect in the case of young persons who have not attained the age of 16 as if for the reference to forty-eight hours there were substituted a reference to forty-four hours."

Sir John explained that at an earlier sitting of the Committee the application of the forty-eight hour week to

young persons was discussed, and he had said the Government would like a reduction if possible before the Bill left the Committee in the permitted hours for juveniles between 14 and 16. The new clause proposed an interval of two years from the commencement of the Act to enable the reduction to be made where interdependence of work in factories would raise complications. There should not be a right to apply in any branch of industry for an extension of reduced hours—which he suggested should be forty four—unless three things could be shown. First, the hours proposed which must not in any case be more than forty-eight, must not be such as reasonably to be regarded as injurious to the health of the juvenile. Secondly, the proper carrying on of the industry must make the proposed modification desirable. Thirdly, the juveniles should engage in work familiarizing them with or helping them to train for processes in which older people were employed and likely to lead to their future employment on a permanent basis.

The Home Office had been in close communication with the trade unions and the employers organizations, and the trades examined included the cotton woollen, engineering, printing, bleaching, dyeing and shipbuilding trades. Some expressed concern as to the effect of the proposal. Team work was common in industry, and would in some cases be dislocated by the proposal, but the mere fact of a need for adjustment or some inconvenience was no reason for not making a necessary and justified change. In the cotton and woollen industries many young persons were members of teams and there would have to be considerable reorganization. He had come to the conclusion that the right figure to include as the lower limit for juveniles was forty four hours which would be convenient if the adjustment took the form of an extra half-day's holiday. The clause did not lay down precisely the manner in which the reduced hours were to be given. He urged that the reduction should be a weekly rather than a daily one. It might be possible for the Home Office when it had experience of the working of the scheme to lay down conditions on the manner in which effect should be given to the clause and Subsection 3 of the clause would give the Home Secretary power to do this by regulation.

Mr RHYS DAVIES said as the Act would become operative on July 1 1938 the new provisions would not come into operation until July 1 1940 whereas the half time system had been abolished nearly at one stroke. He advocated a reduction of the minimum to forty hours. Sir ERNEST GRAHAM LITTLE said public opinion was that for boys and girls between 14 and 16 a limit which permitted work for more than forty hours weekly would not allow a sufficient time for physical training, education, or play. If the Committee pressed the forty hour limit it would carry public opinion with it. Mr RHYS DAVIES moved in the new clause to leave out "forty four" and to insert "forty". The amendment was defeated by 26 to 15. A further amendment, also moved by Mr Rhys Davies to substitute one year for two years in the period of delay before the new clause took effect, was accepted and the clause as amended was added to the Bill.

The Committee then accepted new clauses moved by Mr GEOFFREY LLOYD the first of which provided that young persons working in a factory collecting carrying, or delivering goods carrying messages or running errands should be deemed to be employed in the factory. Another new clause made technical provision for the restriction of hours of employment of young persons in certain occupations including employment at docks wharves quays and warehouses. New clauses granting exceptions for factories operating the five-day week and authorizing the Home Secretary to make exceptions as to the hour of commencement of the period of employment where the exigencies of the trade or the convenience of the persons employed so required were added to the Bill. Mr ELLIS SMITH's proposed clause to make compulsory the setting up of safety first committees in factories employing not less than 100 persons was rejected by 27 to 13 and Mr MANDER withdrew a new clause to ensure the provision and cleanliness of messrooms in every factory. On the latter Mr LLOYD pointed out that the Home Secretary had considerable

powers under Clause 45 and that practically all welfare orders already made included the provision about workmen.

REST IN PREGNANCY

Mr GRAHAM WHITE moved a new clause (Period of rest in the case of confinement) as follows:

Any woman or young person employed in a factory shall be entitled on the production of a medical certificate stating that her confinement will probably take place within six weeks to leave her work, and she shall not be permitted to work during the six weeks following her confinement.

Any woman or young person who shall have left her work under the provision of this section shall be entitled to be re-employed at the end of the period of rest.

Sir ERNEST GRAHAM LITTLE hoped the Committee would not accept the new clause. Hard and fast rules for the treatment of confinements before and after delivery were unscientific. An important aspect of this matter in claiming attention in every part of the world was the spread of abortion. Abortion was being practised in factories by women afraid of being dismissed because of their pregnancy. The maternal mortality from it caused very great anxiety. Twenty five per cent of maternal mortality cases had been shown by statistics to be due to abortion, usually conducted by ill-equipped persons. The suggestion in the new clause was entirely unscientific. The whole question might be much more easily dealt with in the way that was adopted in the munitions factories during the war. At that time women were looked after carefully because they were valuable members of the community, and graded work was found for them during pregnancy. There was no reason whatever why graded work could not be found now in factories for women in that condition. Lady ASTOR did not believe the proposed new clause was practicable, and its adoption would be a disservice to women, particularly if there was not full maternity benefit. Even now women were not allowed to go back to the factory within a month after confinement.

Mr ROBERT HUDSON, Parliamentary Secretary to the Ministry of Health, asked the Ministry not to accept this clause because it was appropriate not to a Factories Bill but to a Public Health Bill and because it attempted to enforce a provision in the draft Washington Convention which depended specifically upon another provision that the woman should receive full and adequate maintenance. At present any woman who got a doctor's certificate to say she was incapable of work was entitled to sign off and receive benefit for four weeks before confinement and in addition no employer was allowed knowingly to employ a woman within a certain period after the date of confinement.

The proposed clause was negatived, as was another clause brought up by Mr WHITE on provision for nursing mothers which ran:

A woman or young person employed in a factory who is nursing her child shall be allowed half an hour twice a day for this purpose and time so allowed shall be included in the calculation of the total hours worked.

Mr HUDSON said the Government was informed by scientific advisers that with the modern shorter working day provisions of this nature were unnecessary that it was sufficient in normal conditions for a woman to nurse her baby before she left for the factory and immediately after she got back, and that provision for one artificial meal for the child in the middle of the working period was better than expecting the mother to go home to the child or arranging for the child to be brought to the factory.

A new clause to make exceptions as to mineral and aerated water factories with respect to the hours of employment of women and young persons where there was seasonal pressure of work was withdrawn. A new clause moved by Colonel SANDEMAN ALLEN on the training and supervision of young persons working on dangerous machines was accepted and added to the Bill.

Certain amendments were made in the schedule to the Bill and the Bill as amended was reported to the House. Sir

JOHN SIMON said the Committee had had twenty-seven sessions, and 580 amendments had been put on the Order Paper, beside a certain number of manuscript amendments. He thanked the chairman of the Committee, Major Lloyd George for his patience and skill.

Thames Barrage Proposal

THE EARL OF DUDLEY in the House of Lords on May 26 advocated a public inquiry into the condition of the River Thames in London and the proposal to build a barrage at Woolwich. He said that a Thames barrage had been mooted for several decades, but no headway had been made towards the public inquiry which was asked for the purpose of examining the proposal. A comparatively simple and an expensive scheme would do away for all time with the ugly and insanitary mud flats on both banks at low tide to the advantage of health safety, public convenience, shipping, and commerce as well as to aesthetic appearances. The project of the Thames Barrage Association was to dam the Thames at Woolwich remove the tides entirely from the London reaches and make the thirty miles of river from Teddington to Woolwich into a slow moving lake maintaining a constant water level. The total cost including all compensation and auxiliary work was estimated at only £4,500,000. There would be a large increase of river transport and a major advantage to public health.

At present 335,000,000 gallons of only partly treated sewage was ejected into the river every day. Of this 81 per cent came from the main works at Barking Creek, of which the outfalls were below the proposed barrage. Most of this was now floated back into London on each flood tide but not carried away to the sea by ebb tides and the ill effect on public health from this pollution was recognized by the Minister of Health. A scheme was under contemplation by the London County Council to take all sewage out of the river into the Channel at a cost of £62,000,000. If the dam were constructed none of this sewage could enter the tideless lake and the remaining 19 per cent of sewage discharged from up-river works could be treated under regulations which could not be enforced under tidal conditions and could be effectively purified in what would then be fresh water.

LORD RITCHIE OF DUNDEE said the Port of London Authority was conversant with this scheme and the opposition of that Authority to it was not due to private interest. As Chairman of the Port Authority he was interested in pollution. The Port of London Act laid upon the Authority the duty of preserving as far as possible the purity of the water. The Authority laid down standards of purity for all effluents discharged into the river. These standards were rigorously imposed but the London County Council was specifically exempted under the Act and the Port of London Authority had no control over it. The County Council's outfall stations at Crossness and Barking discharged into the river every day 280,000,000 gallons of sewage effluent, which had been a source of concern to the Authority for years past especially two or three years ago during the period of drought.

He sympathized with the County Council in the problem with which it had to deal. The promoters of the scheme said their barrage would improve the water of the river. In the opinion of the Authority the reverse would be the result. Above the proposed dam at Woolwich the constant high water would back up the tributary streams into which much sewage matter was discharged and prevent the free discharge which at present took place at low water. This would result in the ponding of highly polluted water and the production of offensive and unhygienic conditions. The sewage storm overflows which discharged untreated sewage into the river would cause offensive conditions when the benefit derived from the tide flush and scouring the river above the dam was withdrawn. Below the dam the pollution of the river water would be of greater intensity than at present owing to the ponding of the sewage discharge of the Barking and Crossness outfalls on the flood tide.

A PREVIOUS EXPERIMENT

LORD DESBOROUGH said that when he was Chairman of the Thames Conservancy that body put up a half tidal weir at Richmond which produced such beneficial results that places below—such as Putney and Wandsworth—asked that a similar weir should be constructed in their neighbourhood to save them from the awful mud flats they had at low tide. At present, in the Thames opposite the Houses of Parliament, the water was neither fresh nor salt. It contained 280,000,000 gallons of moderately filtered effluent, which went up and down at every tide and at slack water went on the mud flats, becoming as Dr Shadwell had said a great menace to London. Lord Desborough denied that the effect on the effluent of this travel up with the tide and down again was to purify it. His information was that there was so much silt in this dirty water that no purification occurred such as would happen if the water were fresh.

LORD SNELL, speaking for the London County Council said the waters of the river were far from satisfactory but the County Council had spent much money in trying to improve the conditions, and in the near future there would be definite improvement. The Council had arrived at no decision on this matter but in the face of the statement made by Lord Ritchie of Dundee the Council until better informed would not be able to take any decision on the barrage. The Council was responsible for disposal of the storm water which came into London. The storm water from the large pumping stations at Abbey Mills and Deptford as well as others would be discharged above the dam, which would contain almost quiescent fresh water.

THE EARL OF ERNE replying for the Government said the main reason that the Ministry of Transport did not favour an inquiry was that Parliament in 1908 gave the Port of London Authority full responsibility for looking after the River Thames. That Authority opposed the scheme. The Minister of Health also opposed the scheme. That Minister considered the barrage would hold up sewage and trade effluents which were discharged above the barrage. It would cause an accumulation at flood tides immediately below the barrage of heavily polluted water which would be deprived of the purifying effective movement with the tide. A condition which was reasonably satisfactory while the Thames was an open river would cease to be so under the new conditions unless heavy expenditure were incurred in more intensive treatment of the effluents. The holding up of land water would increase the risk of flooding above Richmond. The Minister of Transport had been in consultation with the President of the Board of Trade and the President was also unfavourable to the scheme.

Approved Societies' Administration of Benefit

MR PARKER on May 26 asked the Minister of Health whether, in view of the differing practices of various approved societies in the administration of the National Health Insurance Act he would secure the introduction of a uniform system under which the rights of insured persons to benefit were more clearly defined. Mr ROBERT HUNSON said Sir Kingsley Wood had no reason to think that under the system of administration of national health insurance through approved societies insured persons were not aware of their rights to the benefits provided by the Act. As every insured person had a right of appeal if dissatisfied with the decision of his society on a claim for benefit the Minister did not consider that any such fundamental change as was suggested was either necessary or desirable.

Midwifery Services in Wales

MR JAMES GRIFFITHS asked on May 27 whether the Minister of Health having regard to the abnormally high maternal mortality rate in Wales and more particularly in the rural areas was satisfied with the proposals submitted by the appropriate authorities in the Principality for the provision of midwifery service and if not what steps he proposed. Sir KINGSLEY replied that examination of the pro-

posals submitted by the local supervising authorities in Wales under the Midwives Act 1936 was not complete, but in the case of the majority of the authorities their proposals might be considered generally adequate. In some cases further information was awaited and in others points, varying in different areas, were the subject of communication with the local supervising authority. If in any case he was advised that the proposals submitted were inadequate he would make the necessary representations to the authority concerned.

Duke-Fingard Inhalation Treatment

Mr ROWSON on May 27, asked whether the Minister of Health would set up a committee of inquiry consisting of an equal number of medical men and laymen to inquire into the efficacy and genuineness of the Duke-Fingard inhalation treatment for diseases of the respiratory organs such as chronic catarrh, bronchitis, bronchiectasis, asthma and tuberculosis and take steps to have this treatment made available for panel patients under the Health Insurance Acts who suffered from chest complaints.

Sir KINGSLEY WOOD replied that he would not take such action. He was not aware of any sufficient reason for instituting a special inquiry into this treatment. An insurance practitioner was free to give such treatment as in his judgment was appropriate for his patients.

Mr ROWSON: Will the Minister put this treatment on the list of those which may be used by the medical profession for the diseases mentioned in the question?

Sir K. WOOD: The hon. member had better give me notice of that question.

Mr JAGGER: Is the Minister aware that personal friends of mine and numbers of my constituents who had been given up as incurable have been cured by this treatment?

Safety glass—On May 26 Mr HORE BELISHA announced the results of his investigations into the question whether certain forms of safety glass used in motor cars turned opaque when cracked or broken. He said it was found that on the rare occasions when glass of this type cracked without collapsing the obscuration was not complete and the cracked glass could be pushed out. He saw no reason for prohibiting its use.

Coalowners and Silicosis Compensation—On May 31 Mr J. GRIFFITHS asked the Home Secretary if he was aware that the South Wales Coalowners Indemnity Society was refusing to pay compensation to men certified by the medical board to be disabled by silicosis, that the reason given for this refusal was that the society proposed to institute proceedings for the purpose of seeking a declaration that the Silicosis Orders were *ultra vires*, that meantime these men were compelled to seek public assistance and what action he proposed to take in the matter. Sir SAMUEL HOARE said he had no information to the effect suggested and had no power to interfere with any legal proceedings. Mr GRIFFITHS asked if Sir Samuel Hoare would give an assurance, if the courts held that this Order was *ultra vires* that these men would not be penalized, and that the Government would bring in a new Order to give them compensation to which they were entitled. Sir SAMUEL HOARE agreed that this was a matter of great importance but said he would rather not express an opinion until he had further facts.

The Services

INDIAN MEDICAL SERVICE

SPECIAL CORONATION DINNER

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant London on Wednesday June 16 at 7.15 p.m. when Brevet Colonel Sir Rickard Christophers C.I.E., O.B.E., F.R.S. will preside. Officers can arrange to sit near their friends and separate tables to seat eight will be provided. Tickets may be obtained from the joint honorary secretary Major Sir Thomas Carey Evans, Hammersmith Hospital, Ducane Road, London, W.12.

Medical News

The president and council of the Harverian Society of London have issued invitations to the Buckston Browne annual banquet, to be held at the Connaught Rooms, Great Queen Street, W.C., on Thursday, June 10, at 7.30 for 8 p.m.

The first International Congress of Neo Hippocratic Medicine will be held in Paris from July 1 to 5, under the presidency of Dr Laignel Lavastine, professor of the history of medicine in the Paris Faculty of Medicine. Further information can be obtained from the secretary of the congress, Hôpital Leopold-Bellan, 7, Rue du Texel, Paris XIVe.

The twelfth annual Macalister Lecture will be given at the National Temperance Hospital, Hampstead Road, N.W., on Thursday, June 24, at 9 p.m., by Sir Arthur MacNalty, whose subject is "The Doctor in Politics and Diplomacy." All medical practitioners are invited to be present and may bring friends (ladies or gentlemen). Smoking is allowed and tea and coffee will be served.

A Chadwick Public Lecture on 'Plants in Health and Disease' will be delivered by Mr H. Gilbert Carter at the Chelsea Physic Garden, Swan Walk, S.W., on Thursday, June 10, at 5 p.m., with Sir William Collins in the chair.

The third annual general meeting of the British Association of Radiologists will be held at the British Institute of Radiology, 32, Welbeck Street, on Friday and Saturday, June 11 and 12.

The summer meeting of the Association of Clinical Pathologists will be held at the Royal East Sussex Hospital, Hastings, on Saturday, June 12, at 9.30 a.m., when the subject for discussion will be Blood Transfusion and Saline Injections to be opened by Professor A. E. Boycott, F.R.S. Subsequent speakers will be Dr H. F. Brewer, "The Organization and Medical Administration of a Voluntary Blood Transfusion Service," Dr S. C. Dyke, "The Organization of a Blood Transfusion Service," Dr J. Boycott, "Grouping of Donors and Recipients," Dr H. L. Marriott and Dr A. Kekwick, "Continuous Drip Blood Transfusion," Dr R. J. V. Pulvertaft, "Abnormal Reaction following Blood Transfusion," Dr P. Lazarus-Barlow, "Direct Blood Transfusion," Dr F. A. Knott, "Transfusion in Aplastic Anaemia and Agranulocytosis," Dr Norah H. Schuster, "The Storage of Blood," Dr N. Hamilton Fairley, "Intravenous Haemolysis, with Special Reference to Pseudo-Methaemoglobin Production," Dr R. Officer, "Post-operative Saline Treatment." After the meeting members of the Association will be entertained to an official luncheon to be given by the Corporation of Hastings. At the afternoon session Dr Janet Vaughan will show specimens from a case of osteosclerosis with leuco-erythroblastic anaemia, and Dr Lazarus Barlow will give a demonstration of a new method of filtering agar culture media. There will be a business meeting at 5 p.m.

The King Edward's Hospital Fund for London has made arrangements for a second series of Coronation tours of historical buildings famous throughout the Empire. These privileged visits will take place on June 9, 16, and 25, July 7, 14, 16 and 21. Tickets are 10s. each visit (Tilbury Docks £1) or £3 for the series, and the entire proceeds are devoted to the Fund. Communications should be addressed to the secretary, King Edward's Hospital Fund for London, 10 Old Jewry, E.C.2.

The issue of *Paris Médical* for May 15 which is mainly devoted to diseases of the liver and pancreas, shows the distribution of the medical staff in Paris hospitals.

The Belgian Red Cross has sent four motor ambulances to Spain, two for the Government forces and two for the insurgents.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR BRITISH MEDICAL JOURNAL B.M.A. HOUSE TAVISTOCK SQUARE W.C.1

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager British Medical Association House Tavistock Square, W.C.1 on receipt of proofs. Authors over seas should indicate on MSS if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

QUERIES AND ANSWERS

Chronic Proctitis

"PROCTALGIA" writes I should be most grateful for suggestions in treating a case of chronic proctitis. My patient is a middle aged man who had a severe attack of acute proctitis with passage of mucus pus and blood and severe pain. These have now all cleared up with treatment, but pain and discomfort still persist and are aggravated by prolonged standing and particularly by motoring. Suppositories and rectal irrigations give no relief, and the chief complaint is of a burning sensation in the rectum. Recent examination with the proctoscope and sigmoidoscope show the mucous membrane is now normal in appearance and it is difficult to see why the pain should persist.

Mastitis of Puberty in the Male

Dr W. PATERSON BROWN (London W.1) writes I have recently been puzzled to account for a painful non septic mastitis, at first unilateral in an apparently normal boy of 16. There was no history of mumps or other condition which might be responsible and I obtained no enlightenment from the standard textbooks which I consulted. I now find an adequate account of the disorder in the *Year Book of Neurology, Psychiatry and Endocrinology* (1936 p. 578). Apparently it is a by no means rare complication of puberty in boys may last for months but generally resolves and requires no treatment. I am writing this note in the hope that others encountering the same condition may be saved from being as puzzled as I was.

Splitting of Finger Nails

"H. M. B. F." writes It is just possible that the following may prove helpful to "Stumped" who asks if anyone can suggest a cause for the splitting and flaking of his wife's finger nails. The condition may be due to nail varnish especially when this varnish is used to remove the old layer before painting on the new one. I have found that the condition can be cured by using an oily remover for taking off the old varnish. There are several brands of oily remover on the market.

Another correspondent writes A discussion on cases of peculiar splitting of the nail was opened in the Section of Dermatology of the Royal Society of Medicine by Dr A. C. Roxburgh and was reported in the *Proceedings* of that society for February 20 1936. I have seen a number of cases since of a similar type and have come to the conclusion that the splitting of the nails is due to the use of nail varnish and the splitting of the nails is due to the use of nail varnish and nail varnish remover. As the nails take some five months to grow from the nail fold to the free edge stopping the use of nail varnish will not be followed by an immediate cure.

Asthma Query

Dr A. B. JOHNSON (Chautauqua, New York) writes in reply to "Plex" (*Journal* May 1 p. 952) I have had excellent results with the intratracheal injection of lipiodol. It seems to me that this treatment warrants a trial in "Plex's" case injecting 4 to 5 c.cm. as indicated. I should be glad to supply him with all the details as to technique if he should so desire. It should be understood that the lipiodol is used therapeutically and not necessarily diagnostically a fact which is not yet commonly appreciated.

Income Tax

Sale of Share in Partnership

A. B. C. asks (a) When one partner buys out the other and works the practice with an assistant is the surviving partner in any way responsible for the income tax of the partner who has gone? (b) Are legal expenses incurred in purchasing the share allowable expenses?

*(a) The profits of a partnership are assessable on the firm as such for the period to the date of dissolution of the partnership and the tax is legally recoverable from either partner. As regards the subsequent period "A. B. C." will presumably require the practice to be regarded as having started afresh at the date of dissolution so that he can deduct the salary etc. of his assistant. (b) No such expenses are of a capital nature.

LETTERS, NOTES, ETC

Gangrene Complicating Diphtheria

Dr EUSTACE THORP (Sunderland) writes Few cases of gangrene complicating diphtheria are mentioned in the literature. I have recently had three grave cases. In the first about six square inches of the left side of the frontal bone were denuded and there were numerous small spots of gangrene over the skin obviously embolic. Diphtheria bacilli were recovered from the discharge. In the second there was extensive gangrene of the left side of the neck exposing the sterno mastoid and the muscles of the posterior triangle diphtheria bacilli were again recovered. There were no other gangrenous sites. In the third a gangrene of the cheek like that in the second resembled noma. All the cases occurred in poor children and the condition was present before admission to hospital.

Medical Aid in Spain

Mr GEORGE JEGGER, Organizing Secretary, Spanish Medical Aid Committee (24 New Oxford Street W.C.1) writes The work being done in Spain by the British Medical Unit has received widespread publicity and assistance has been forthcoming to the extent of £30,000 from people of all political views. Members of the medical profession have been particularly generous and it is therefore with some diffidence that I appeal to them again through your columns. But the shortage of medical supplies of all kinds is so acute that little things that are practically valueless in England are necessities in Spain. Might I ask doctors who do not make use of the samples so frequently sent them by druggists to send them to us? Our hospitals can use them. If desired they can be collected.

Hawthornberry Jam

R. L. METTING (*Zbl. inn. Med.* April 3 1937 p. 289) describes the method of preparation of hawthornberry jam and hawthornberry infusion. These when suitably prepared represent a rich source of vitamin C. Experiments on animals have proved that the jam possesses marked antiscorbutic properties. Guinea pigs artificially infected with pneumococcus were favourably influenced by the administration of the jam. The advantage of the hawthornberry as a source of vitamin C is that of being available all the year round.

Corrigendum

In Major S. N. HAYES's paper on "Present-day Methods of Sterilizing Dressings" which appeared in our issue for May 1 a printer's error occurred eight lines from the foot of the first column of page 913. It was there wrongly stated that to sterilize efficiently six abdominal sheets in an autoclave perforated drum would take 72-80 minutes. The time taken should have read 72 + 20 minutes.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

440 Nervous Complications in Leukaemia

P MASSAROLI (*Polichinco Sez. Med.*, April 1, 1937, p 177) records a personal case, and has collected from the literature between 1878 and 1933 thirty-two other cases, of nervous complications of the different forms of leukaemia. As a general rule they are a late manifestation in an obvious case of leukaemia, but they may be the first symptom of the hitherto unrecognized disease. Nervous complications are more frequent in lymphatic than in myeloid leukaemia, as is shown by the fact that in twenty-five cases in which sufficient haematological data were available nineteen were examples of the former and only six of the latter. The nervous complications which are most often encountered are partly due to haemorrhage and partly to leukaemic infiltration of the tissues. As regards the former, simple or multiple cerebral haemorrhages are most frequent, haematomyelia is less common, and haemorrhagic pachymeningitis is rarest of all. The complications due to leukaemic infiltrations are most often found in the nerves, especially the cranial nerves, then in the spinal cord, the brain, and the meninges. A third and much rarer type of lesion consists in combined degeneration of the spinal cord, which is exactly similar to that found in pernicious anaemia. Massaroli's patient was a girl aged 19, in whom involvement of the cranial nerves was marked at the onset of lymphatic leukaemia, diabetes insipidus occurred in the last stage.

441 Benign Tuberculosis of Adolescents

A PIC and M PIÉRY (*J méd Lyon* March 5, 1937, p 123) in 2,300 medical inspections, conducted during twenty years, of candidates for the *Écoles Normales* aged 15½ to 18, have found a syndrome which they describe as indicating a benign tuberculosis of adolescents and differing from the tuberculous syndromes both of infancy and of adult life. In 38 per cent. of the males and 35 per cent. of the females two or more of the following were found: intermittent or orthostatic albuminuria, anaemia, thyroid hypertrophy, cervical or axillary adenopathy, kyphoscoliosis. Morbid physical signs, usually at one pulmonary apex, were found in a few of these subjects, but all who were subjected to x-ray examination showed hilar enlargement. Each individual component of the syndrome described has been stated by French writers to be that of a pretuberculous state or mild tuberculous infection, and such a syndrome in adolescents corresponds closely with the "inflammatory tuberculosis" of Poncet and Leriche. Following up these adolescents for a year or longer, Pic and Piéry have found that persistence of pulmonary infection is very exceptional (and then in an attenuated form), and that the majority of these subjects show great improvement in signs and symptoms after a few months rest by the sea or preferably, in mountain climates.

442 Fate of the Young Diabetic

W STOCKINGER and H ALBRECHT (*Med Klinik* March 5, 1937, p 335) point out that diabetes in the young is usually of a severe type. In the pre-insulin era the prognosis was very grave: of twenty-five patients treated in 1921-3 only one is alive to-day. Since the introduction of insulin the prognosis is very much better: of 106 patients treated between 1923 and 1935 48 per cent are alive. The authors discuss the mortality, which is still high: (1) It is due in 25 per cent to complications of which tuberculosis is the most serious (13 per cent). Complications which occur typically in adult diabetics are rarely found in the young, death due to hypoglycaemic

shock is uncommon. (2) 75 per cent. of fatal cases are due to coma. Coma is followed by death because treatment has been begun too late owing to the poor economic environment of the patient or a lack of knowledge on the part of his doctor. Lack of self-discipline on the part of the patient in the carrying out of his diet or the administration of insulin is followed by coma and death. Infection is a grave danger to the young diabetic. It lowers the tolerance permanently at the beginning of the disease. In old-standing cases stabilized by insulin administration infection is only temporarily serious. An average daily dosage of 50 to 60 units of insulin is necessary in young diabetics for the maintenance of health. Although diabetics are eugenically inferior, the majority are an economical asset. Of forty-eight young diabetics under the authors' care only three are unable to work, fourteen are able to work part-time and thirty one whole-time. The self-discipline necessary for the overcoming of their condition makes the majority psychologically more fit to face life. Hard manual labour is not necessarily contraindicated. Work requiring much nervous energy is usually unsuitable owing to the danger of hypoglycaemia. Work entailing special difficulty with regard to diet and insulin therapy must be given up. State appointments are generally not open to diabetics.

Surgery

443 Phlebitis following Trauma

M C LASSERRE (*Gaz hebdomadaire de médecine* March 28, 1937, p 200) states that phlebitis following trauma is not uncommon, and describes ten cases of which four were fatal, occurring within three months, in all of them the lower limb was involved. The age of the patients varied from 25 to 72, but the commonest age was between 35 and 50 years. In five cases pulmonary embolism revealed the presence of phlebitis, in two cases the phlebitis remained latent. Most of the patients were restless. Round about the tenth day following the trauma the temperature was elevated and the pulse accelerated, and pain was complained of. Sudden death occurred in four cases twenty to forty days after operation on the lower limb. Lasserre believes that in most cases death is due to microscopic or fat emboli, or to massive emboli with pulmonary infarction. Necropsies are rarely performed and their results are often inconclusive. For prophylactic and remedial treatment he recommends complete immobilization of the limb and the application of leeches to soft parts in which attrition and haematomata are present.

444 Catgut

J E RHOADS, H F HOTTENSTEIN and I F HUDSON (*Arch Surg* Chicago, March, 1937, p 377) review the medical literature on the absorption of catgut. Catgut must be sterile, strong, supple, and absorbable. Much experimental work has been carried out on the effect of various methods of sterilization on the tensile strength of the catgut, and suppleness has also been studied by determining the loss of tensile strength that results from knotting. Tests have been made on different kinds of catgut, and showed variation between consecutive samples from the same strand of catgut, between different strands of catgut of the same size type and brand, between sizes 0 and 1 of otherwise identical catgut, between corresponding products of different manufacturers and between plain, medium, hard, chromic, and tanned iodized catgut of the same size and from the same manufacturer. Tests by means of the implantation of different kinds of catgut in the abdominal walls of dogs showed that tanned iodized

catgut possessed substantially more resistance to the action of tissue fluids and was less affected by infection than medium hard chromic catgut. It was also ascertained that tanned iodized catgut loses its strength more slowly both in dogs and in man than medium hard chromic catgut. Detailed results of all these tests are given, with the history of the development and preparation of catgut during the last hundred years.

445 Thyroidectomy in Heart Disease

T S CLAIBORNE and L M HURXTHAL (*New Engl J Med* March 11, 1937, p 411) give the results of total thyroidectomy in twenty-seven patients with heart disease. There were fourteen cases of angina pectoris, in two of which there was associated congestive heart failure. Eight of the patients had hypertension, and four had rheumatic heart disease with valvular lesions. In this group there were no operative deaths, although three patients died subsequently, two in under four months, from rheumatic heart disease with an aortic lesion, while recurrence and death occurred at the end of a year in the third case. The eleven living patients have been followed up for from one to two and a half years, and improvement has been over 50 per cent in five cases, between 25 and 50 per cent in five cases, and only slight in the remaining case. The degree of improvement appears to have diminished slowly since the first year after operation. Total thyroidectomy was carried out in thirteen cases of congestive heart failure. Eight patients had rheumatic heart disease with valvular lesions, two had syphilitic heart disease, and three hypertensive heart disease. There was one operative death in this group, and six patients have since died. There was no real improvement in eight cases, there was definite, though temporary improvement in one case, and definite and gratifying improvement in four cases. Armour's desiccated thyroid was used to control symptoms of myxoedema in all cases. A brief summary of each case is given. Although the results have been fairly satisfactory in some cases, it was seen that the amelioration of pain in cases of angina pectoris was more or less temporary. The conclusion reached as a result of total thyroidectomy in this series of cases is that the operation is justifiable in some cases, but that they are few in number.

446 Retroperitoneal Tumours

E HESSE (*Presse méd* March 31, 1937, p 492) draws attention to what he calls a calorimetric symptom of diagnostic value in cases of tumour or inflammation in the retroperitoneal space. This symptom is caused by the pressure of the tumour or the extension of the inflammatory condition, producing compression of the lumbar part of the sympathetic trunk where it passes over the antero-lateral aspect of the vertebrae. This compression leads to lowering of the skin temperature, hyperhidrosis, and exaggeration of the pilomotor reaction of the lower limb. If the pressure on the nerve continues or if the tumour increases the phenomenon of excitation gives place to inhibition and later to paralysis. Clinically this is manifested by elevation of the temperature, the diminution and loss of sweating and then disappearance of the pilomotor reflex of the corresponding lower limb particularly at the ankle. This group of symptoms is of great diagnostic value particularly the difference in temperature of the two limbs which can be felt by the back of the hand. The hyperhidrosis or anhidrosis is also appreciable to the touch. The excitation of the sympathetic trunk produces an exaggerated sweating and the skin of the leg is moister than on the other side. Paralysis of the nerve causes a dryness of the skin. Eight cases are reported in which these symptoms established a diagnosis of tumour or inflammatory condition in the retroperitoneal space when a correct diagnosis would have been impossible in the early stages by any other means.

1182

Therapeutics

447

Peripheral Vascular Diseases

K HITZENBERGER (*Wien klin Wschr* April 9, 1937, p 465) points out that in organic diseases of the peripheral blood vessels treatment of the pain and of the underlying cause is indicated. Pain may occur in the veins and arteries themselves. It is combated by placing the affected limb at rest. Drugs which enlarge the vessel lumen are useless. Care must be exercised in the application of heat, for diseased blood vessels often give a paradoxical reaction to heat, which may cause gangrene. Pain occurs in organs which are ischaemic owing to a poor blood supply from diseased vessels. In such cases rest is essential. In cases of reversed intermittent claudication in which pain occurs during rest case is obtained by having the limb hanging down. Where pain is due to infection care must be taken in the choice of well fitting shoes and in the cutting of nails and corns. In the presence of gangrene conservative treatment with rest, warm baths, and ointments containing thyroxine must be tried before any surgical intervention. Treatment of the cause is directed towards increasing the lumen of the blood vessels. In thromboangiitis obliterans Hitzenger has had excellent results for over six years with follicular hormones, 1,000 units of menformon are injected daily for three weeks and the injections repeated at six monthly intervals. Operation has never been required. He came to use this form of therapy because this condition occurs nearly always in men, and he believed that a female sex hormone might act as a protection against the disease. Other conditions of the peripheral blood vessels react less certainly to follicular hormones. Owing to a raising of the viscosity of the blood in some of these conditions the administration of hypertonic saline is useful, 150 to 300 ccm of 5 per cent salt solution are injected two to three times weekly for from six weeks to two years. The author also strongly recommends the use of increased and decreased pressure artificially produced in treatment. The limb is placed in a boot, hermetically sealed above to which pumps regulating the pressure within it are attached. An increase of pressure to +20 mm Hg for one to three seconds is enough, otherwise thromboses occur. Pressure may be decreased to -80 mm Hg, not lower, otherwise haemorrhages into the skin occur. Daily treatment lasts two to six hours, and the whole course 100 hours. Phlegmonous conditions and acute thrombophlebitis, but not gangrene or varicosis, are contraindications to this form of therapy.

448

Treatment of Erysipelas

S SCHWARTZ (*Thèse Paris* 1937, No 127) records ten illustrative cases in children aged from 15 days to 24 years including a personal case in a male child aged 3 weeks with generalized erysipelas complicated by gangrene of the scrotum. Recovery took place after the administration of prontosil in large doses. About a hundred cases reported by other writers testify to the good results obtained in erysipelas in older children and adults so that Schwartz comes to the conclusion that prontosil may be regarded as a specific for erysipelas in young children.

449

Gold Tribromide in Whooping-cough

J EPSTEIN (*Arch Pediat* March 1937 p 177) records his observations on 350 cases of pertussis, 191 being girls and 159 boys aged from 3 weeks to 81 years. Nine cases had had a prophylactic vaccination from one to 14 years before the onset of whooping-cough. 250 were given gold tribromide exclusively while 100 were treated by drugs such as sodium bromide, antipyrin, phenobarbital and camphorated tincture of opium. The results were

as follows. Under gold treatment the average duration of the cough was three to eight weeks, while among the controls it was ten weeks. After considerable experimenting the gold tribromide was finally made up in a stable, assayed, and palatable elixir. The average dose for children was a teaspoonful every four hours, and for adults two teaspoonfuls.

Dermatology

450 Intolerance to Resins

M. FERRAND, H. RABEAU, and UKRAINCZYK (*Bull Soc franç Derm Syph* January, 1937, p 77) describe a case of dermatitis of the hands in a painter. This began on the thumb and forefinger of each hand and spread over the whole of both hands and forearms. The eruption was papulo-vesicular in type and intensely itching in character. Patch tests were performed with a number of substances used in his work, and were found to be positive only in the case of varnishes and oils containing turpentine resins. It is of interest to note that the patient had been a painter for over forty years before becoming thus sensitized, and that he subsequently was able to return to work employing only water colours or distemper. A year after the trouble had cleared up he was found by patch tests to be still sensitive to the same substances.

451 Argyria

A timely warning is issued by A. W. STILLIANS (*Arch Derm Syph* Chicago, January, 1937, p 67) against the haphazard and wholesale use of silver preparations. According to him argyria is on the increase. This is largely due to the fact that assertions made by the manufacturers of proprietary colloidal and organic silver preparations—that they do not cause argyria—are untrue. Silver is most readily absorbed from the stomach and intestines, but it is also absorbed from any other part of the body, and is soon deposited in the skin where, on histological section, it is found to be present in the corium. Clinically in argyria the skin is a bluish colour in the parts exposed to light and an ashy grey where it is covered. The diagnosis may be confirmed by injecting intradermally a mixture of 1 per cent potassium ferrocyanide and 6 per cent sodium thiosulphate in distilled water. This causes the appearance of a light spot. The same solution may be employed for treatment of the condition but although results are good the method is a tedious one.

452 Pyoderma and Psoriasis

F. FRENZL (*Derm Wschr* January 16, 1937, p 81) discusses the relation between psoriasis and pyoderma. The history of persons suffering from psoriasis often reveals an attack of more or less extensive furunculosis preceding the outbreak of the psoriasis. In such cases the furunculosis is supposed to have weakened the vitality of the individual and thus contributed to the manifestation of the psoriatic diathesis. The same explanation applies to cases where the pyoderma appears simultaneously with the psoriasis. In a number of cases, however, the pyoderma appears after an attack of psoriasis, sometimes even after the psoriasis has been apparently cured. In such cases the psoriatic diathesis has been weakened to such an extent as to allow the development of ordinary pyodermic manifestations.

453 Juvenile Acne

F. MILANES (*Arch Soc Estud clin Habana* January 1937 p 13) records his observations on forty-four cases of acne in patients whose average age was 21. With three exceptions all were females, thirty-seven of whom were

unmarried. The majority were of a slender build, had a certain degree of thyroid abnormality, a normal basal metabolism, morphological changes of the suprarenal type (hirsutism) and complained also of functional dysmenorrhoea. The majority therefore presented a syndrome involving the ovaries, suprarenal cortex and thyroid, arising from impaired ovarian function and closely associated with the development of puberty. As regards the digestive system a large proportion showed symptoms of a hepatobiliary type such as dyspepsia, abdominal pain, diarrhoea, and constipation. A syndrome of marked intestinal fermentation was also present as shown by naked-eye, microscopical, bacteriological, and chemical examination of the excreta. The pathogenesis of acne therefore appears to consist in a hepato-endocrine syndrome, which is responsible for changes in the sebaceous system of the skin, in which septic factors play a secondary part. Treatment consequently should be both local and internal, the latter consisting in the administration of the appropriate endocrine extracts.

Obstetrics and Gynaecology

454 Adnexal Tuberculosis

T. HEYNEMANN (*Zbl Gynäk* March 27, 1937, p 738) has found neither in his own investigations nor in the literature a single case in which vaginal (conjugal) infection has been proved to be the cause of adnexal tuberculosis, the reported cases break down either because a thoracic focus has not been excluded radiographically or because it has been forgotten that acid-fast bacilli in the semen of a male suffering from urogenital tuberculosis may be smegma bacilli, and that therefore only animal inoculation tests are conclusive. He states that experience has now convinced most gynaecologists that conservative climatic treatment, although requiring at least six months, is better and less risky than surgery. An adjuvant is found in x-radiation, which, however because of the danger of castration is only justified in the worst cases. Operative treatment is called for only (1) when the diagnosis is obscure, (2) for simple opening of an abscess, (3) when the patient demands it for persistent fistula. Regarding operation as dangerous and to be avoided whenever possible, Heynemann, to ensure a diagnosis, advocates puncture of the pouch of Douglas. Two positive results after animal inoculation and one finding of tubercle bacilli have previously been described after this procedure. Heynemann reports having tried it in eleven patients, with five positive and five negative correct results and one incorrect one in which no fluid could be aspirated. Since smegma bacilli have been found by Simmonds in an adnexal tumour animal inoculation results are more reliable than those of smears. A positive finding in Heynemann's opinion, is a contra-indication to operation.

455 Cancer of the Cervix

K. F. B. BUSCH (*Ugeskr Laeg* March 11, 1937 p 288) reports from a radium centre in Denmark the results he has achieved in cancer of the cervix with radium supplemented since 1931 by x-ray treatment a month after the last radium application. The 653 cases 393 of which were in the third and fourth stages of the disease treated between 1914 and 1927 were reviewed after an interval of at least five years, when it was found that recoveries could be claimed in 68 per cent. of the cases in all four stages of the disease. The recovery rate after an observation period of only three years after treatment was 24.8 per cent. Wishing to see if the supplementary treatment with the x rays has appreciably increased the recovery rate, the author has investigated the after-histories of the 69 patients treated during 1932. In forty of these cases the patients were in the third or fourth stage of the

disease After an observation period of three years, 40.6 per cent of the patients were still symptom free. If a discount of 10 per cent be allowed for the next two years after the first three years following treatment, the calculation may be made that approximately 30 per cent of the patients first treated with radium and then with x rays would be symptom-free five years later. The rise from a recovery rate of 16.8 per cent to 30 per cent is in the author's opinion, not to be accounted for by the slight rise in the proportion of early cases treated in 1932, and he is inclined to credit the post-radium treatment with x rays with at least some of this improvement. Still better results should be possible if (1) education of the public brought patients to treatment earlier, (2) more attention were paid to avoiding local infections, (3) preliminary and larger doses of x ray treatment were given, and (4) the radium were distributed in a more suitable way.

456 Hegar's First Sign of Pregnancy

A-MAYER (*Zbl Gynäk* April 3, 1937, p 786) upholds the reliability of Hegar's first sign, which, he says, has many times saved him from operating in pregnancy for supposed ovarian cyst or myoma as diagnosed by others. Hegar's sign has recently been subjected to criticism by Russian writers, who never found it positive during the first three or four weeks. In reply Mayer suggests that owing to the frequency of abortion, and therefore of endometritis, in Russia many of the uteri examined were not sufficiently healthy to show the softness and elasticity which form the basis of the test. It would seem too, that of late years it has sometimes been forgotten that Hegar's sign consists in a compressibility not of the cervix, but of the lower part of the corpus uteri. Finally, administration of a general anaesthetic, which is absolutely necessary in those with a fat or rigid abdominal wall, is sometimes wrongly omitted. Mayer finds Hegar's sign reliable in the great majority of healthy uteri, especially in primiparæ.

457 Histological Diagnosis of Pregnancy

B. G. SMITH and E. K. BRUNNER (*Amer J Obstet Gynec* March, 1937, p 404) as a preliminary to their investigation of the typical histological changes of the vaginal mucosa in pregnancy have first studied the normal and the most common pathological microscopical appearances of the vaginal mucosa. These appearances are described in detail. In the fifty-four cases of pregnancy represented by 110 biopsies of the vaginal mucosa the histological diagnosis of pregnancy was positive, and was possible in the very early stages of pregnancy. In four cases a positive diagnosis was made when menstruation was only six days overdue. The principal defect of the method is that it is not applicable in cases exhibiting marked pathological modifications of the vaginal mucosa, as for example in chronic vaginitis etc. The advantage of the method is its speed. The biopsies are small, and the usual paraffin technique can be speeded up so that the sections are ready for study in a few hours.

Pathology

458 Morphine Detection

C. K. LIANG (*Chin med J* February 1937, p 211) describes a new method for the detection of morphine in the urine. Fifty ccm of urine are acidified with tartaric acid and evaporated to a syrupy consistence on a water-bath, then well mixed with 5 or 6 grammes of clean dry sand and evaporated to dryness. The residue is extracted with 30 ccm of warm alcohol (95 per cent) three times filtered and the alcohol evaporated. The residue is mixed

with 25 ccm water, transferred to a separating funnel and neutralized with sodium hydroxide (25 per cent), 1 ccm of phosphoric acid (85 per cent) is added then 10 ccm of amyl alcohol to remove the colouring impurities. The aqueous solution is separated and made alkaline with ammonia. It is then extracted twice with 10 ccm of amyl alcohol and the extract purified by shaking out with 10 ccm of normal phosphoric solution (3 per cent) twice. The phosphoric acid solution is made alkaline with ammonia and shaken out with chloroform-alcohol mixture (9:1). The residue from the chloroform-alcohol extract is tested for morphine by means of Froehde's, Froehde, Buckingham's, or Marquis's reagents. The author claims that this method will detect 0.005 mg of morphine hydrochloride in 50 ccm urine, and that it is much less costly and time-consuming than other methods. Also the test can be done with 50 ccm of urine, whereas other methods require 500 ccm.

459 Heart Lesions in Scurvy

J. MCBROOM *et al* (*Arch Pathol* January, 1937, p 20) have studied the effects of scurvy on the guinea pig heart in the presence and absence of streptococcal infection. Four groups of eight to ten guinea-pigs were used. Two groups were fed on a diet producing acute scurvy. One of these, together with a third group on a semi-scorbutic diet and the fourth on a normal diet, were injected with haemolytic streptococci. Marked degenerative and proliferative valvular lesions were found in the majority of guinea pigs that died of acute scurvy and were equally prevalent and severe whether or not there was a superimposed streptococcal infection. The animals on a semi-scorbutic diet with a superimposed streptococcal infection showed evidence of acute scurvy. The fourth group (control) of guinea pigs showed no evidence of scurvy and only few heart lesions. Focal haemorrhages and focal degeneration with some proliferative reaction were seen in the myocardium of those animals with acute scurvy. The heart lesions were different from those in rheumatic fever, although there were points of resemblance. There was no evidence that rheumatic fever and scurvy are the same disease or have a causal relationship, although scurvy may be indirectly a factor in lowering resistance to infection and infection may precipitate acute scurvy in semi-scorbutic states.

460 Blood Changes After Exercise

T. TSUCHIYA (*Jap J exp Med* December, 1936 p 551) has studied the changes in the blood cells and tissues of dogs produced by running (treadmill) exercise of varying duration and degree, the course of recovery, and the effects on the recovery rate of injections of various tissue constituents. Both erythrocyte and leucocyte counts immediately after exercise were transiently higher than before but as exercise increased in duration and severity the erythrocytes began to show advancing diminution in numbers while the leucocyte count first increased and then decreased, with changes in the distribution of the cells. The haemoglobin content ran parallel to the erythrocyte count. Depending on the duration and severity of the exercise recovery from the anaemia caused by prolonged exercise was found to occur spontaneously and the leucocyte count returned to normal sometimes with leucocytosis and eosinophilia. The histological changes in the haemopoietic organs usually indicated hypo-erythropoiesis and accorded with the blood changes. Changes in the kidney—glomerular hyperaemia, cast formation, capillary haemorrhages etc.—agreed with the findings in the urine after exercise. Changes in the liver, spleen and lungs were noted. All these tissue changes were recovered from in about one month after cessation of exercise. Of the tissues injected only erythrocytes and marrow cells appeared to have any appreciable effect in assisting recovery from the exercise anaemia.

Illustration shows three diverticula of the sigmoid one in cross section

Diverticula of the sigmoid area are of special clinical importance. Here, the pouches are most likely to become filled with faecal residue resulting in ulceration and possibly perforation.

A desirable measure of prophylaxis in the prevention of diverticulosis changing into the inflammatory stage of diverticulitis is to promote adequate intestinal evacuations.

For this purpose, AGAROL is admirably adapted by reason of its composition. Agarol combines highly purified mineral

oil, agar-agar and phenolphthalein in a stable emulsion of microscopic fineness.

By softening the intestinal contents, lubricating their passage, and by gently stimulating peristalsis, Agarol leaves no doubt that evacuation will take place fully regularly and painlessly. Agarol has no contra-indications. It is suitable for all ages and in all conditions where an evacuant is indicated. It is acceptable to all palates. Its consistency makes for accuracy and uniformity of dosage.

'VARIBAN' ELASTIC PLASTER BANDAGE

VARIBAN BANDAGE constitutes a marked advance on the older methods of treating chronic ulceration of the leg. It is made from a specially woven s-cyclo material possessing highly elastic properties and is impregnated with an antiseptic zinc oxide paste.

VARIBAN is self-adhesive and combines the principles of firm equable pressure and support to the swollen leg with the benefit of an occlusive dressing under which the ulcer is protected and is stimulated to healthy repair.

In promoting proper circulation **VARIBAN** steadily reduces oedema. It provides protection to the granulations of the healing ulcer. In the majority of cases it is found that pain is either eliminated or greatly relieved from the first application. The necessity for ointments, lotions, etc. is obviated while **VARIBAN** provides an ambulatory treatment which allows of full activity of the limb with better results than those following rest in bed alone.

An investment in the stocks and shares of British Investment Trust Companies selected to provide a safe and expanding income

INVESTMENT TRUST UNITS

After any period of depression investment trust companies are among the last to reflect recovery. While shareholders in the majority of industrial companies have already enjoyed the 1934-35 recovery in the shape of higher dividends, shareholders in investment trust companies, owing to the 'time-lag' factor, have only recently started to benefit. Units may be purchased and full particulars obtained through any Stockbroker or Bank.

The Managers of Investment Trust Units estimate an initial gross yield based on cash dividends after allowing for management charges, of not less than 4 per cent.

Lloyds Bank Limited are Custodian Trustees of the underlying securities of Investment Trust Units; they collect the dividends on the underlying securities and distribute the income to Unit holders.

RENDLESHAM HALL

(Postal Address) — **WOODEPIDGE, SUFFOLK**

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT

A Course of Lectures on **PATHOLOGICAL RESEARCH IN ITS RELATION TO MEDICINE** has been arranged for the **SUMMER SESSION**. These Lectures will be given in the Lecture Theatre of the Bacteriological Department of the Institute, on **TUESDAY AFTERNOONS** at 5 p.m. The sixth and seventh Lectures of the series will be the following —

JUNE 8th

WILSON SMITH M.D.

Subject

"The Influenza Problem"

(Member Scientific Staff National Institute for Medical Research)

Syllabus furnished by the Lecturer —

The Lecture deals with the intensive research on Influenza carried out since the virus was first isolated in 1933

Many virus strains have now been isolated in widely separated parts of the world by means of ferret inoculation these strains if not identical are very closely related antigenically. The ferret virus has been adapted to mice and cultivated both in tissue culture and on the chorio-allantoic membrane of the chicken embryo

The study of Influenza in experimental animals has yielded much information concerning the characteristics of the immunity which follows infection. To both ferrets and mice a considerable degree of resistance can be conferred by prophylactic vaccination. The efficacy of different vaccines have been compared and attempts made to obtain purified and concentrated products suitable for use in man

The antibody response following vaccination of humans encourages the belief that epidemic Influenza will eventually be preventable, but results obtained during the recent epidemic 1936-7 show that the main Influenza problem is still far from solution

JUNE 15th

Salary—£750 to £850 by annual increments of £50.

Quarters—Unfurnished quarters are provided free.

Passages—Free passages will be provided on first appointment for the officer and his family not exceeding four persons besides himself.

Terms of Appointment—The appointment is provisional subject to a period of two years probation.

Duties—The general direction and superintendence of the Asylum.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service) 2 Richmond Terrace Whitehall London S.W.1

BOROUGH OF HESTON AND ISLEWORTH

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

Applications are invited from duly qualified medical men with a Public Health qualification for the position of Assistant Medical Officer of Health and School Medical Officer.

Candidates will be required to carry out medical inspection of school children, bacteriological work, child welfare work, and administer dental anaesthetics and perform such other duties as may be allotted as a member to the Medical Officer of Health and School Medical Officer.

The person appointed will be required to devote his whole time to the duties and will be allowed to engage in private practice. The salary will be at the rate of £1,000 per annum rising to £1,200 per annum by increments of £25 per annum.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers Superannuation Act 1922, which has been adopted by the Council and the appointment will be subject to a period of medical examination in connection therewith.

Copies of the appointment form and terms of appointment may be obtained from the Medical Officer of Health 94a, Bala Road, Heston.

Applications should be sent to the Council of the Borough of Heston and Isleworth, 100, Victoria Road, Heston, by 10.15 a.m. on June 11, 1937.

COUNCIL HESTON AND ISLEWORTH
J. H. W. JONES, Town Clerk

SOUTHERN RHODESIA MEDICAL SERVICE GOVERNMENT MEDICAL OFFICER

Applications are invited from fully qualified medical Practitioners for appointment as a GOVERNMENT MEDICAL OFFICER in the Southern Rhodesia Medical Service.

Salary will be on the scale £600-£25-£750 per annum. There is also a senior grade (£750-£25-£900) to which promotions are made as vacancies occur. Salary will commence from the date of assumption of duty in Southern Rhodesia. In addition private practice is allowed.

The successful applicant will be required to sign an agreement for three years service in the first instance and thereafter may make application to be placed on the pensionable establishment.

A free second-class steamship passage to Cape Town and first-class railway ticket thence to Southern Rhodesia will be provided.

Conveying either directly or indirectly will disqualify applicants.

The applicants should state the date on which they would be prepared to leave England if appointed.

Applications stating age, qualifications and experience together with copies of testimonials, should reach the Official Secretary Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London W.C.2 (from whom further particulars and application form may be obtained) not later than June 15th.

LIVERPOOL COUNTY BOROUGH

LOCAL EDUCATION AUTHORITY

ASSISTANT SCHOOL MEDICAL OFFICERS

Applications are invited for TWO ASSISTANT SCHOOL MEDICAL OFFICERS in the Department of the Medical Officer to the Local Education Authority at a salary in each case of £500 per annum rising by annual increments of £25 to £700 per annum.

(Where a successful candidate holds a similar appointment under another Local Education Authority and receives a salary in excess of the advertised minimum a commencing salary of not less than the salary which the candidate is receiving under his (or her) existing appointment (not exceeding the maximum under the Liverpool Scale) may be paid.)

Candidates must be registered medical practitioners and must have had at least three years experience. It is desirable that they should have had some special experience in school hygiene and in diseases of children.

The Officers appointed will be required to reside within the City and devote whole time service to the Local Education Authority under the direction of the Medical Officer to the Local Education Authority and will not be allowed to undertake any private practice.

The appointments will be subject to the Local Government and Other Officers Superannuation Act 1922 and the Standing Orders of the City Council.

Form of application which may be obtained by forwarding a stamped addressed foolscap envelope, should be returned together with copies of three recent testimonials, to the undersigned not later than June 21st 1937 and endorsed Assistant School Medical Officer.

The conveying of Members of the Education Committee or the City Council is strictly prohibited and will be considered a disqualification.

W. H. BAINES
Town Clerk and Clerk to the Local Education Authority

Municipal Buildings Liverpool 2.
June 4th 1937

THE KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION

Applications are invited from duly registered medical practitioners (male) for the post of ASSISTANT TUBERCULOSIS MEDICAL OFFICER (resident) at the Sully Hospital, Sully, Glam. (400 beds) for the treatment of pulmonary tuberculosis) situated between Penarth and Barry.

Salary £500 per annum rising by annual increments of £25 to £700 per annum less the value of emoluments amounting to £100 per annum.

Preferably candidates should have six months' resident experience in a special institution (Hospital or Sanatorium) for the treatment of pulmonary and/or non-pulmonary tuberculosis with eighteen months' experience in general clinical work of which six months' should have been spent in a hospital not confined to the treatment of tuberculosis. Experience in anaesthetics also desirable.

The person appointed to the above post will be required to pass a medical examination and to receive 5 per cent of his salary (the 5 per centum being paid of the actual amount and not of the gross) in the form of a Medical Pension in the event of his death or retirement.

Applications should be sent to the Secretary, The King Edward VII Welsh National Memorial Association, 10, Victoria Road, Heston, by 10.15 a.m. on June 11, 1937.

11 St. James' Street, Manchester 1.
May 11, 1937

COUNTY COUNCIL OF MIDDLESEX. CENTRAL MIDDLESEX COUNTY HOSPITAL. WILLESDEN

Applications are invited for the following appointments at the above hospital. Candidates must be registered medical practitioners unmarried and must have held resident appointments in a general hospital.

TWO RESIDENT ASSISTANT MEDICAL OFFICERS (Male)

Salary £400 per annum rising by annual increments of £25 to £475 per annum together with board lodging and laundry valued at £100 per annum.

The duties of one of the appointments are mainly surgical and candidates must have had special experience in surgery.

For the other appointment candidates must be experienced in the administration of anaesthetics by modern methods and special qualification in anaesthetics is desirable.

The appointments which do not carry any rights under the Council's Superannuation Act are for a period of four years at the end of which period the officers will leave the Council's service. In a special case the Council may decide to retain an officer on the established staff in which case the salary will be increased to a maximum of £500 per annum.

RESIDENT CASUALTY MEDICAL OFFICER.

Salary £350 per annum with board lodging and laundry valued at £100 per annum.

The duties of this officer will be carried out mainly in the admission and outpatient department. Higher qualifications are desirable and previous hospital and surgical experience essential.

The appointment is for a period of six months with the option of renewal for a further period of six months if desired and on the recommendation of the Medical Superintendent.

Each of the appointments which will be subject to medical examination will be held during the pleasure of the Council and are terminable by one month's notice on either side.

The officers appointed will work under the direction of the Medical Superintendent of the Hospital and will devote their whole time to their official duties.

Applications stating age qualifications and experience together with copies of not more than three recent testimonials must be received by the undersigned not later than June 12th. Application forms are not provided. Envelopes must be endorsed "Resident Medical Officer (Surgical) (Anaesthetic) or (Casualty) Central Middlesex County Hospital" as the case may be. Relation ship to any member or officer of the Council must be disclosed in the application.

Canvassing directly or indirectly will be a disqualification.

C. W. RADCLIFFE, Z.
Clerk of the County Council

Must Man Remain Unknown?

In the current (June) issue of *The Modern Mystic*, appears the first of a series of articles under the above title by Eugen Kolisko, M D (Vienna). In some measure the articles will take the form of a reply to some of the questions raised by Dr Alexis Carrel in his recently published "Man—The Unknown". *The Modern Mystic* is the only journal of its kind in the World.

OLEO-SANOCRYSIN

The original Gold preparation for
RHEUMATOID ARTHRITIS

You don't buy a sphygmomanometer every year, so why not have a genuine Lifetime Baumanometer. First cost may be a little more, but *through the years* it actually costs less.

Baumanometer is the registered trade mark which identifies only the product of the W. A. Baum Co. Inc., New York. Originators and Makers of Bloodpressure Apparatus Exclusively since 1916. No instrument is a genuine Baumanometer unless it is so marked.

The Test of Time

We have been making the Baumanometer now for some twenty-one years, which is a long while to devote exclusively to the making of *any* one thing.

And in all of that time our work has never deviated from these three principles:

ACCURACY—above all else, the rock upon which the Baumanometer first won the medical profession's confidence.

SIMPLICITY—the "irreducible minimum" number of parts, especially valves or joints to leak air pressure or mercury.

RELIABILITY—to the end that whatever variation is found, you may be sure it is in the patient, and *not* in the instrument.

To-day our most cherished asset is the confidence, and good will, and respect of doctors and hospitals throughout the world. The Baumanometer has stood the test of time.

SCHOOL CHILDREN ESPECIALLY . . . ARE FOND OF THIS PURE FRUIT JUICE

GOOD work, as every doctor knows, is very often dependent upon good health. And a well regulated diet is important for maintaining good health.

Dole Hawaiian Pineapple Juice is the natural juice of sun-ripened, Dole-grown pineapples. It contains no added sugar or preservatives of any kind.

The exclusive Dole Fast-Seal Vacuum Packing Process retains, to a high degree, those important fresh fruit constituents found in the ripened pineapple so valuable, not only to growing children, but to adults as well! Also, this tangy, tropical juice is a natural source of vitamins A, B and C. That's why with schooltime, when parents are asking about diets and menus for their children, you can recommend with assurance pure, unsweetened Dole Pineapple Juice—the original pineapple juice from Hawaii.

J. K. Husband & Co., Ltd., 10 Eastcheap, London, E.C.3

HERE IS A TYPICAL ANALYSIS OF DOLE PINEAPPLE JUICE :

Moisture	85.3%	Crude Fibre	0.02%
Ash	0.4	Titrateable acidity as citric acid	0.9
Fat (ether extract)	0.3	Reducing sugars as invert sugar	12.4
Protein (N x 6.25)	0.3	Carbohydrates other than sugars (by difference)	0.38

P.S. We would like you to enjoy a long cool glass of this refreshing juice! Write to us on your letterhead and we will send you a sample tin free.

THE LEI WOMAN—An old Hawaiian custom ever new is the habit of decorating departing or returning friends with beautiful wreaths of native flowers. The fragrant ilima, maile, plumeria, pikake and ginger are used extensively in the making of leis. It is a picturesque sight on steamer days to see the native women with their skilful hands weaving the fragrant garlands.

MARMITE

(YEAST EXTRACT)

For vitamin B₁ and
vitamin B₂ complex

The value of supplementing restricted diets with Marmite, for its high vitamin content, is becoming increasingly appreciated. It is considered particularly beneficial in diabetes and colitis. An authority outlining the dietetic treatment of gastro-duodenal haemorrhage states —

' Marmite is given at least once a day for the vitamin B complex (Brit Med Journ April 24th 1937 p 847)

As a therapeutic agent in disorders associated with deficiency of vitamin B₁ or the B₂ complex, Marmite is prescribed extensively. In a recently published paper, referring to pellagrous conditions, case reports are quoted which illustrate

' the dramatic effect of Marmite on the skin lesions (Lancet May 22nd 1937, p 1225)

Marmite is also ordered for its specific haemopoietic properties in the treatment of certain forms of anaemia.

For sample and literature apply to —

ANAHÆMIN B.D.H.

In Pernicious Anæmia

Anahæmin B.D.H. presents in a high degree of purity the active haematopoietic principle of liver which has been separated from the reaction-producing protein substances. Although the constitution of anahæmin is not yet elucidated, its characteristics are sufficiently well-known and standardised to ensure the issue of a product which is unvarying in

chemical composition as well as in anti-anæmic potency.

The uniform therapeutic activity of Anahæmin B.D.H. is guaranteed by clinical tests upon actual pernicious anæmia cases, and, in addition, every batch is required before issue to pass stringent biological, chemical, physical and bacteriological tests.

IODATOL, 40 PER CENT.

For use in X-Ray Diagnosis

Iodatol, 40 per cent, a pale, viscous oily fluid, opaque to X-rays, conforms with the official specification for iodised oil—*Oleum Iodatum* (Addendum 1936 to the *B.P.* 1932)

The injection of Iodatol, 40 per cent as a means of conducting explorations of various delicate organs and cavities of the body is regarded as a routine procedure

In bronchiectasis it makes possible a complete investigation of the bronchial tree, in spinal disease it renders possible the diagnosis of spinal cord tumour. It is employed in salpingography, in suspected pulmonary tumours and in the exploration of abscesses and fistulae.

Iodatol also finds a useful place in therapeutics.

"ALOCOL"

Colloidal Hydroxide of Aluminium

Rational Antacid Therapy

A PART from those cases due to actual organic disease, the treatment of the syndrome of symptoms known as indigestion, generally resolves itself into an attempt to overcome hypersecretion of acid and to soothe the irritated or inflamed gastric mucosa

That Alocol possesses intrinsic qualities which render it particularly valuable as a gastric sedative and antacid is now well established. Its freedom from the constipating effect of bismuth and the laxative action of magnesium salts and the gas forming properties of sodium bicarbonate are especially noteworthy.

Alocol forms with the gastric contents a colloidal jelly which has the power of adsorbing free hydrochloric acid. Its markedly soothing effect on the gastric mucosa promptly relieves pain and discomfort. It does not interfere with the normal process of digestion and is free from the danger of 'alkalosis'.

Complete chemical history of Alocol with convincing clinical reports and supply for trial sent free to physicians on request

FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research, acetyl-salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has however caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that Alasil definitely solves the problem of administering acetyl-salicylic acid in an effective form being free from the risk of irritating the stomach or bowels or of causing general reactions.

A supply for clinical trial with full descriptive literature sent free on request

In "Alasil" the desirable therapeutic effects of acetyl-salicylic acid are well exhibited by its calcium acetyl-salicylate moiety while the presence of "Alocol" (Colloidal Hydroxide of Aluminium) a powerful gastric sedative and antacid obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

TRUFOOD BABIES

BECOME STURDY CHILDREN

A DOCTOR'S SON

*who was fed in infancy
on Humanised
Trufood*

The theory behind Humanised Trufood is the simple one that the mother's milk is the best food for an infant and that any substitute infant food should resemble human milk as closely as possible. Analysis of Humanised Trufood shews it to be virtually identical with human milk. The sturdiness of children who have been fed on Humanised Trufood, and their absence of digestive troubles in infancy, is convincing evidence of the soundness of this theory

STARCH

AND ITS DIGESTION

STARCH is Nature's solution of the problem of storing Carbohydrate To safeguard the plant's 'hoard,' starch *has* to be insoluble, and the grains are protected by resistant capsules of cellulose Of biological necessity, therefore, 'raw' starch, as it occurs in plants, is indigestible

The 'conversion' of starch into soluble derivatives is essential for its absorption as food by the animal, and the enzymes of the saliva and of the pancreatic juice convert it into soluble carbohydrates

In the case of man and his staple food, bread, the 'conversion' of starch is started by the processes of milling, leavening and baking applied to it before it is eaten Baking not only ruptures the cellulose capsules of the starch granules, but it also converts much of the starch of the flour into 'soluble starch' and into 'halfway' products such as dextrin

These important changes are most advanced in the crust of bread, or in toast, and they account for the greater digestibility of those forms of bread Vita-Weat excels toast and crust The thin, crisp slices are very thoroughly baked, and a very large proportion of the starch in Vita-Weat is 'converted'

into dextrin and soluble starches

It is useful to remember that fact when prescribing a diet for the commonest form of dyspepsia — carbohydrate dyspepsia In this common complaint much of the starch in the food is hurried through the small intestine and reaches the caecum undigested It then gives rise to bowel flatulence, and a sense of fullness and discomfort

A change to Vita-Weat will often aid digestion very greatly in such patients It is a change, be it remembered, not from bread to some special form of biscuit, but from ordinary bread to a *crispbread* in which most of the starch has been changed into a readily digestible form

THE BRITISH WHOLE WHEAT CRISPBREAD

MADE BY PEEK FREAN MAKERS OF FAMOUS BISCUITS

Pregnancy and Lactation

Most Nurses at times experience difficulty in persuading female patients to drink sufficient water to ensure the ordinary processes of metabolism being sufficiently carried out.

During pregnancy Andrews will be found of great service. Its pleasant saline taste and refreshing qualities make it a very acceptable draught, which can be repeated with advantage twice or thrice daily if necessary, thus obviating the tendency to constipation and relieving hepatic congestion and haemorrhoids without drastic purgation and its consequent risks at this period.

In the persistent vomiting of pregnancy the sedative effect of "Andrews" will be found helpful, and its aperient action is of great value in cases of renal insufficiency.

During lactation it will be found most useful for the relief of constipation as Andrews does not produce any violent disturbance in the system and it leaves the secretion of milk unaffected.

A NEW FEATURE

Each tin of Andrews is now sealed by a patented damp-and dust proof Cellophane Cap, which maintains original Laboratory condition making a good product even better

An 8-oz Tin will be sent free, on request, to any member of the Medical Profession

Andrews Liver Salt

Scott & Turner Ltd., Andrews House, Newcastle-on-Tyne, 2

A major operation in progress in the operating theatre of a London hospital

THE DANGER OF INFECTION

It is not only in the operating theatre that the value of antiseptic protection is to-day recognised. Men and women in everyday life are learning the importance of germ-free cleanliness. More careful attention to hygiene is resulting in better standards of health.

Of course, it is not possible in everyday hygiene for ordinary people to take such elaborate precautions against infection as those taken by the surgeon before an operation. Nevertheless, protective measures against the daily risks of infection are obviously needed, and it is generally accepted that the simplest and probably the most effective protection is that given by washing exposed parts of the body, such as the hands and face, regularly with a reliable antiseptic soap.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for health protection for over 70 years. It has substantial antiseptic and antipruritic qualities, and is made from the costliest materials obtainable. It is the only soap in the world to contain 'liquor carbonis detergens' (Wright's), the valuable skin therapeutic recommended by leading dermatologists. An investigation by the Institute of Industrial Psychology reveals that more doctors themselves use Wright's than any other brand of toilet soap. You are safe in recommending Wright's to your patients—and in using it in your own practice.

Formula

Intestinal glands -	- 0 05 grms.
Biliary extract -	- 0 10 "
Lactic ferments -	- 0 05 "
Agar-agar -	- 0 05 "
Fiat tablet -	- 0 35 "

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics

- 1 They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
- 2 They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained

Taxol has both these advantages

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

BULK

in modern diet

CHRONIC CONSTIPATION YIELDS TO BRAN REMEDY

The problem of balancing up the lack of bulk in diet and so ensuring normal bowel action is one which is solved by the addition of Kellogg's ALL-BRAN to the diet. ALL-BRAN is a natural laxative food and is rich in Vitamin B and iron.

ALL-BRAN cleanses like a *water-softened sponge*. Within the body the soft "bulk" of ALL-BRAN gently exercises intestinal muscles, and

sponges out the system ensuring natural and regular elimination. Some patients eat Kellogg's ALL-BRAN, served from the packet, with cream or milk. Others prefer it cooked into biscuits, cakes or omelettes.

Except in cases of hyper-sensitive digestive tracts Kellogg's ALL-BRAN can be safely and confidently prescribed. Full-sized sample packet free on request.

Rx Calcium Aspirin Tabs
(Genasprin Brand)
T.T. T.D.S. ex. aq.

CHOREA

From information received —

I have used Calcium Aspirin (Genasprin Brand) in a male aged 8 years in a mild but intractable case of chorea (Sydenham's) hitherto of 8 weeks previous history and no improvement with arsenic chlorotone or sod sal. I gave the patient 7½ tablets twice daily in divided doses actually 4 doses each day following food for one month. The case completely recovered after one month on Calcium Aspirin.

When I heard of the Calcium Aspirin my case a female aged 13 years had been in bed six weeks with severe chorea and was then showing definite signs of improvement. After one week's treatment with Calcium Aspirin 15 grs t.d.s., improvement was very rapid and the exhibition of Calcium Aspirin was stopped and now the patient seems quite well.

I have had excellent results with Stabilised Calcium Aspirin in severe cases of chorea in several adolescent males and females ages varying from 10 to 15 years. I gave the patients from 5 to 15 grs three times a day over a period of three to six weeks. The twitching movements were controlled early and there was no evidence of over-dosage with salicylates. In addition most of the children have found this preparation to be extremely palatable.

I gave Calcium Aspirin 15 grs t.d.s. to a female patient aged 28 years who was suffering from chorea and have never seen a case of this kind make such rapid improvement.

I have found Calcium Aspirin excellent in all my cases of chorea.

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

The Treatment of *Epidermomycosis*

THE prevalence of fungous infections of the skin, as typified by ringworm of the feet or "athlete's foot," has been recognized in recent years. Contributions to medical literature have stressed the fact that such infections are far more common during the summer months than was at one time supposed. In fact, they are considered by some dermatologists to take a foremost place amongst common skin affections.

The successful treatment of infections due to *trichophyton* and *epidermophyton* is considerably facilitated by the use of Mycozol, an ointment containing salicylic acid, mercury salicylate and Chloretone, in a base that is readily absorbed by the skin so as to permit intimate contact of the active ingredients with the deeper layers.

Mycozol produces rapid maceration, and the separation of the horny layers of the epidermis, thus exposing the fungus to its inhibitive action.

A liquid preparation (Liquid Mycozol), for use as a paint in conjunction with the ointment, contains salicylic acid and benzoic acid, together with Chloretone and malachite green.

Full particulars concerning Mycozol and Liquid Mycozol will be furnished on request.

AN OUTBREAK OF MILK-BORNE SCARLET FEVER AND TONSILLITIS IN DONCASTER

by

R. WATSON, M.A., M.B., D.P.H.

Medical Officer of Health, Doncaster County Borough

Many outbreaks of tonsillitis and scarlet fever due to the drinking of infected milk have been reported, but the outbreak which occurred in Doncaster in December 1936 had several points of interest which appear to make it worth while adding to the literature on the subject. The outbreak was a comparatively small one extending over a period of not more than twelve days from December 9 to December 20 inclusive and as the infected milk amounting to about fifty gallons a day all came from one farm and was distributed by one retailer unmixed with milk from other sources investigation was made comparatively simple. The number of cases affected however is large enough to warrant certain conclusions being drawn.

Source of Infection

The first cases came to my notice about midday on December 11 and by the evening of that day fifteen cases of scarlet fever had been notified, all in the same part of the town. Suspicion fell on a certain milk supply and arrangements were made for four samples of this milk to be taken for bacteriological examination that afternoon. Later in the day sufficient evidence had been collected to warrant a notice being issued under the Milk and Dairies Acts and Orders prohibiting the sale of this

December 15, and the milk when not pasteurized was then used for other purposes and not distributed direct to consumers.

Bacteriological Investigations

In the meantime it had been found that the milkman suspended from duty had a child who had been suffering from otorrhoea since December 2 and that he had been dressing the ear. On December 14 arrangements were made with Dr. Griffith of the Ministry of Health Laboratory for the typing of the haemolytic streptococci which had been found to be present in the discharge from this child's ear and in swabs taken from the throats of the milkers and several of the patients who had been admitted to the isolation hospital. On December 15 the cows forming the herd supplying the infected milk were examined by the chief veterinary officer of the West Riding County Council, Major D. S. Rabagliati, and group samples were submitted to Dr. Griffith for examination. The only clinical abnormality discovered in the herd was that one of the cows was suffering from an induration of one teat, the condition being diagnosed as a crushed teat. It was stated to have been crushed by a tread about a fortnight previously. There was no external lesion.

Only a few cases associated with the milk supply were notified in the rural district area, and these do not materially affect the total figures

Very early in the outbreak it was noticed that many patients had only tonsillitis with no signs of a rash. In an attempt to obtain a complete picture of the effect of the mass infection I have recently completed an investigation of all the families known to be taking the milk during the period in which it was infected. The results of this inquiry are shown in the following tables and charts.

The milk was delivered by the retailer to 380 families in Doncaster, and of these 205 families (54 per cent) were affected to a greater or less degree, the infection being fairly equally distributed over the whole area of supply. The 380 families contained 1,343 persons and were made up as follows: children aged 0 to 4 years, 62; children aged 5 to 14 years, 218; persons aged 15 years and over, 1,063. The number of persons attacked and the attack rates are shown in Table I.

TABLE I—The Number of Persons Attacked and the Attack Rates in Varying Age Groups

Age Group (Years)	No. of Persons at Risk	Cases of Scarlet Fever	Cases of Sore Throat	Total Cases Affected
0-4	62	26 (41.9%)	8 (11.3%)	34 (53.2%)
5-14	218	53 (23.9%)	37 (16.9%)	90 (40.8%)
15 and over	1,063	56 (5.3%)	184 (17.4%)	240 (22.7%)
Totals	1,343	135 (10.0%)	229 (17.0%)	364 (27.1%)

TABLE II—Cases of Scarlet Fever and Sore Throat due to Infected Milk. Age and Sex Distribution (December 1936)

Age Group (Years)	Scarlet Fever Cases			Sore Throat Cases			Total Cases Attacked		
	Males	Females	Total	Males	Females	Total	Males	Females	Total
0-4	16 (26.2%)	10 (13.5%)	26 (19.2%)	4 (4.2%)	4 (3.0%)	8 (3.5%)	20 (12.7%)	14 (6.7%)	34 (9.3%)
5-9	13 (21.3%)	20 (27.0%)	33 (24.4%)	8 (8.4%)	7 (5.2%)	15 (6.5%)	21 (13.4%)	27 (13.0%)	48 (13.3%)
10-14	10 (16.4%)	10 (13.5%)	20 (14.9%)	11 (11.4%)	11 (8.4%)	22 (9.6%)	21 (13.4%)	21 (10.3%)	42 (11.5%)
15-19	3 (5.0%)	9 (12.1%)	12 (8.9%)	11 (11.4%)	7 (5.2%)	18 (7.9%)	14 (8.9%)	16 (7.7%)	30 (8.2%)
20 and over	19 (31.1%)	25 (33.9%)	44 (32.6%)	62 (64.6%)	104 (78.2%)	166 (72.5%)	81 (51.6%)	129 (62.3%)	210 (57.7%)
Totals	61 (100%)	74 (100%)	135 (100%)	96 (100%)	133 (100%)	229 (100%)	157 (100%)	207 (100%)	364 (100%)

TABLE III—Cases of Scarlet Fever in Doncaster other than those due to Infected Milk (1935 and 1936)

Age Group (Years)	Male	Female	Total
0-4	16 (21.8%)	27 (13.4%)	63 (17.2%)
5-9	61 (76.9%)	84 (41.6%)	145 (39.5%)
10-14	49 (29.7%)	94 (24.7%)	99 (27.0%)
15-19	5 (1.0%)	7 (3.5%)	12 (3.3%)
20 and over	14 (8.6%)	34 (16.8%)	48 (13.0%)
Totals	165 (100%)	202 (100%)	367 (100%)

These figures are interesting as they show how, with presumably the same infecting organism, the incidence of a rash symptomatic of scarlet fever appears to vary according to the age of the person attacked. Having regard to the number at risk in the different age groups, they also seem to indicate how much more children are affected than adults, especially children under 5 years of age. They also bear out findings collected by Professor Picken (1936) to the effect that in a milk outbreak adults may form a large proportion of the total cases suffering from clinical scarlet fever. The distribu-

tion of cases, of both scarlet fever and sore throat, according to age and sex is shown in Table II. For comparison with the scarlet fever group the distribution of these cases for the years 1935 and 1936 (excluding those cases associated with the milk outbreak) is appended (Table III). These latter figures should form a fair basis of comparison, as they do not include any cases which were associated with a milk-borne epidemic.

So far as cases of clinical scarlet fever were concerned in the milk outbreak the percentage of the total cases occurring among adult males was nearly four times the normal expectation. Among adult females the percentage was about twice the normal. Children of school age in proportion showed a lower percentage incidence than the normal rates would lead one to expect. The effect of the outbreak must, however, be judged on the total number of cases of tonsillitis and scarlet fever, for which, unfortunately, no comparison with the normal expectation is possible. From the figures in Table II it will be seen that among males 51.6 per cent of the total cases of scarlet fever and tonsillitis were adults, and for the adult females this figure was 62.3 per cent. The only comparable figures are those respecting the Chelmsford outbreak, to which the Doncaster figures approximate fairly closely. It is of interest to know that both the Chelmsford and the Doncaster outbreaks were caused by a Type II haemolytic streptococcal infection of milk. No evidence has been forthcoming to account for the high percentage of the adults attacked, possibly this might be due to a previous absence of Type II infection in the areas.

Course of Outbreak

The accompanying charts, which show the day-to-day occurrence of cases, whether of tonsillitis or scarlet fever, according to the ascertained date of onset of the disease are of some interest in showing the course of the outbreak and the effects of action taken to bring it to an end. Chart I shows the number of 'milk' cases, of both scarlet fever and tonsillitis, the 'seasonal' cases of scarlet fever being superimposed. From the chart it would appear that the milk outbreak can be limited between December 9 and December 20. The two cases occurring on December 5 and 6 respectively might not be associated with the milk outbreak and the two cases appearing on December 23 and 27 respectively were, so far as can be ascertained, secondary cases. Other ascertained secondary cases were noted as follows: December 13 one case; December 14 one case; December 17, three cases; December 18 three cases; and December 19 two cases. There may have been more secondary cases but without definite proof of this secondary character could not be established the cases have been counted as original milk infections.

The omission of these secondary cases makes it clear that there were no new cases from mass infection of the milk after December 17, and this would correspond with the fact that infected milk ceased to reach consumers after midday on December 15. The odd cases with an

Streptococci pyogenes Type II were isolated on December 15 as the infected milk could not have directly infected the milk after December 11. The infection of the cow's teat was clearly at an early stage when first discovered but Dr Minett has reason for believing that this cow was

CHART 2.—This shows the day-to-day occurrence of cases of scarlet fever and tonsillitis associated with infected milk in different age groups and sexes.

or shooting pain in the throat, and many patients were almost able to state the hour at which this symptom occurred. Some two hours afterwards they had difficulty in getting undressed when they realized that it was imperative that they should go to bed. There were, of course, several cases of a very mild nature, but the majority of patients were suffering sufficiently severely to necessitate their staying in bed for several days.

The throat conditions appeared to vary, but could be roughly divided into the three main types described by Dr Camps in the Chelmsford cases (1935). The cases of scarlet fever were noted as being of a much more serious type than those normally seen. Rash, when present, tended to be marked and to be of a rather coarse nature, desquamation followed the normal course. In the more severe cases pain was a marked feature, and the tonsillar glands were easily palpable. An interesting point is that one dog (an Airedale) appears to have been affected, though the nature of the infection was not confirmed bacteriologically. It became ill a day before any human case occurred in that particular household, became rapidly collapsed, with marked swelling and obvious pain in the region of the fauces, and was described as being "paralysed" for a week.

Complications

The chief complications noted were adenitis, otitis media, quinsy, and polyarthritic symptoms. One case of nephritis, one of acute appendicitis, and one with a diffuse herpetiform eruption were associated with initial throat infections. These complications made their appear-

ance, but this was by no means the case, as in the early days of the outbreak the presence or absence of a rash was often the deciding factor in the request for removal to hospital, and many of the cases showing no signs of a rash were acutely ill. Nor is it believed that the assessment of complications was very much more accurate among cases nursed in hospital. As will be mentioned later, the possible cause of the comparatively large numbers of complications among the hospital patients was that cross infection occurred owing to the admission of cases of scarlet fever associated with a coincident "seasonal" outbreak of the disease.

For all cases the percentages of complications were as follows: in the 0 to 4 age group, 38.2 per cent; in the 5 to 14 age group, 25.5 per cent; in patients aged 15 and over, 25.4 per cent. This gave a total incidence of 26.6 per cent. These percentages are high and the results serious. Apart from many cases suffering from resultant debility there is little doubt that a late spread of infection from the cases of adenitis and otorrhoea resulted in an increased number of cases of scarlet fever in the district during the three months succeeding the outbreak, and has been responsible for an outbreak of tonsillitis with associated scarlet fever in the Doncaster Royal Infirmary which necessitated the closing of one unit for a short period.

Two deaths have definitely been associated with the epidemic—one in a child aged 2 years suffering from severe scarlet fever, who died within twenty-four hours of the onset of the disease, and one in a male aged 33, who developed adenitis following a severe attack of ton-

TABLE IV—*The Incidence of Complications in Cases Treated in Hospital as Compared with those Treated at Home*

Cases Treated in Hospital							
Age Group (years)	Adenitis	Otorrhoea	Quinsy	Arthritic Symptoms	Total Cases	Total Complications	Percentage Incidence of Complications
0-4	—	1 (4.0%)	—	2 (10.0%)	20	3	15.0
5-14	6 (16.2%)	5 (13.5%)	—	4 (10.8%)	37	15	40.5
15 and over	1 (2.2%)	1 (2.2%)	1 (2.2%)	7 (15.5%)	45	10	22.2
Totals	7 (6.8%)	7 (6.8%)	1 (0.9%)	13 (12.7%)	102	28	23.8
Cases Treated at Home							
0-4	5 (35.7%)	5 (35.7%)	—	—	14	10	71.3
5-14	4 (7.5%)	1 (1.9%)	2 (3.8%)	1 (1.9%)	53	8	15.1
15 and over	18 (9.2%)	—	11 (5.6%)	22 (11.3%)	195	51	26.2
Totals	27 (10.3%)	6 (2.3%)	13 (4.9%)	23 (8.8%)	262	69	26.4

ance at intervals varying from three days to three weeks after the onset of the illness, but the majority were seen at the end of the first week. The arthritic symptoms tended to appear a little later than this and were very persistent. They were not the transient joint pains common with streptococcal throat infections; many patients were still complaining of these arthritic pains three months after the outbreak had ended.

Although the figures are too small to be of much value it is interesting to compare the occurrence of complications among those cases nursed in hospital and those nursed at home as shown in Table IV.

From these figures it would appear that except in the 0 to 4 years age group hospital treatment does not appear to have had any beneficial effect upon the reduction of complications. All cases treated in hospital received streptococcal antitoxin (scarlatina) serum but only two cases nursed at home received any serum. It might be argued that only the worst cases were admitted to hos-

pital. One other death was that of a woman aged 38 who developed clinical scarlet fever on December 6 and cannot therefore be definitely associated with the outbreak, although she was taking the milk which later proved to be infected. In all cases death appeared to be due to toxæmia. Unfortunately post mortem examinations were not possible nor were swabs taken at the time of the original throat infections for bacteriological examination. It is worth while noting that no cases of puerperal fever occurred during this period or the succeeding months and that only one case of erysipelas was definitely associated with the outbreak.

Administrative Problems

From the administrative point of view several problems were raised. Once the outbreak had begun it was quickly realized by the general practitioners that the cases of tonsillitis and scarlet fever were of the same origin and the question arose as to whether all cases should be

notified as scarlet fever. Several cases exhibiting no exanthem were in fact notified. This accounts for the fact that the figures in this report do not exactly correspond with those in a preliminary annotation published in the *British Medical Journal* (1937, 1, 26). Rightly or wrongly it was decided to ask for notification only in cases of clinical scarlet fever. In view of the fact that direct case-to-case spread was very limited once the outbreak had begun, the notification of all cases of tonsillitis irrespective as to whether they were associated with the milk infection would have served no useful purpose. It would have been only of limited statistical value unless every case could have been properly investigated by the sanitary inspectors or health visitors as is done in all cases of notifiable infectious disease, and this would have placed an unbearable strain on these staffs whose services at that time were much more usefully applied in other directions.

With regard to isolation hospital accommodation the question of the presence or absence of a rash did not apply. It is true that the majority of cases admitted to hospital were cases of clinical scarlet fever, but cases of tonsillitis were admitted where nursing facilities at home were inadequate. One patient with tonsillitis who developed an acute appendicitis was admitted to hospital for operative treatment, as was also a case of diffuse herpetiform eruption clearly associated with a recent throat infection. One child who had been nursed at home with scarlet fever and had developed otorrhoea was removed to hospital as his mother was expecting to be confined. When home facilities were satisfactory, therefore, cases were nursed at home, but, nevertheless, between December 5 and December 29, 131 patients were admitted to hospital, 102 of these being cases associated with the milk outbreak. Luckily the hospital was nearly empty at the beginning of December, but even then the patients in the sanatorium section had to be given "Christmas leave" to create extended temporary accommodation for scarlet fever cases.

Patients were retained in hospital for three weeks unless complications had ensued. No "return" cases have come to my notice. Some patients developed secondary attacks of tonsillitis in their third week, and this was probably due to cross infection from "seasonal" cases. Some of the "complications" may have been due to this cause. At the very beginning of the outbreak it had been realized that the sudden spate of cases would probably be infected by an organism of one serological type and they were accordingly separated from the few cases of scarlet fever already in hospital. Unfortunately as will be seen from Chart 1 what was apparently a "seasonal" outbreak of scarlet fever began about the same time as the milk outbreak and with the rush of cases it proved impossible to segregate cases strictly according to their probable source of infection, and cross infection occurred. These "seasonal" cases were mainly associated with haemolytic streptococci Type IV, though there was one case of Type I infection which ended fatally. The difficulties associated with cross infection were however most noticeable during the three months succeeding the milk outbreak when as has been stated there was an increase over the usual expected number of scarlet fever cases.

During the period of the outbreak typing of haemolytic streptococci from patients was carried out by Dr Griffith at the Ministry of Health Laboratory. Following the outbreak through the kindness of Dr Camps of Chelmsford all new scarlet fever admissions to hospital have been typed. The point of interest is that, despite the heavy Type II infection in the milk outbreak, this type completely disappeared during the six weeks following

the end of the outbreak and was replaced by a bewildering number of different types which made segregation in hospital a matter of great difficulty. About the middle of February Type II organisms again began to appear, only to disappear early in March.

The other main administrative actions taken early in the outbreak were to inspect the schools in the district chiefly affected to exclude all children showing signs of sore throat and to recommend their parents to obtain medical advice, and to circularize the doctors in the district regarding the epidemic. This circular letter pointed out that few immediate secondary cases were to be expected, but that danger would arise from cases of otorrhoea, etc. resulting from the infection. The danger was made apparent early in January when a few cases of mastoiditis and adenitis found their way to the wards of the Royal Infirmary and precipitated the throat infection there already referred to. The circular also advised the following quarantine periods:

Cases of scarlet fever and severe tonsillitis—three weeks from the date of onset

Cases of mild tonsillitis—one week after the subsidence of symptoms

Cases with throats positive for haemolytic streptococci—one week if no clinical signs of infection appeared. (A good number of these cases were found as interest grew, and caused considerable administrative difficulties.)

Contacts especially school children were advised quarantine for one week unless negative throat swabs had been obtained.

The midwives were also circularized and advised to take special precautions for a considerable period, and the necessity for wearing adequate masks was re-emphasized. All visiting was stopped at the Municipal Maternity Home. Several administrative problems of a minor nature occurred during the course of the outbreak, and with these, as with the greater problems much help was obtained from the Ministry of Health, and especially from a personal visit by the late Dr Vernon Shaw, who visited Doncaster on December 16.

Summary and Conclusions

1 An outbreak of scarlet fever and tonsillitis due to infection of a milk supply with *Streptococcus pyogenes* Type II, and the administrative action taken to minimize the effects of the outbreak are described and discussed.

2 The distribution of cases shows a heavy attack rate among pre school children, and also that adults form a larger proportion than normal of the total cases.

3 The primary infection of the milk appears to have been by the cow becoming infected, but on the evidence obtainable locally the possibility of direct contamination of the milk by a milker cannot be entirely disregarded.

4 The complications subsequent upon infection are enumerated, and from this point of view, apart from children under 5 years of age, hospital treatment appears to have been of doubtful value.

5 The only adequate method of controlling an outbreak is by stopping the milk supply or by having it efficiently pasteurized.

6 To avoid a sense of false security being given in the search for haemolytic streptococci in milk small group samples must be taken.

My thanks are due to Dr F. Griffith, Dr F. C. Missett, and Dr F. E. Camps for the help and for advice they have given to me in the preparation of this report.

THE ADRENAL CORTEX ITS SUPPOSED FUNCTIONS AND SUGGESTED USES OF CORTICAL EXTRACTS*

BY

W. N. KEMP, M.D.
Vancouver B.C. Canada

The adrenal gland has been the object of intensive research since Thomas Addison, in 1855, first disclosed its relation to a comparatively uncommon disease, to which his name has been attached. The massive volume of literature on this relatively small paired gland is scarcely commensurate with our factual knowledge of its function in normal physiological processes (Grollman 1936). In spite of its smallness the adrenal gland must exert a vital influence in the organism, for the surgical removal of both glands soon leads to a complete breakdown of normal function in most of the organs and tissues of the body, rapidly terminating in death.

Each adrenal is situated in the posterior part of the abdomen, overriding the upper pole of the kidney like a 'triangular cocked hat with rounded corners'. The mammalian adrenal is a compound organ formed by the union of two originally separate tissues—namely, the cortex and the medulla. The cortex, which anatomically and physiologically constitutes the chief part of the gland, is usually of a deep yellow colour, due to the presence of lipids, while the medulla is small and pulpy and of a dark reddish colour due to the presence of blood.

In man and the anthropoid apes the medulla is a post-natal development, being represented at birth by a small strip of undifferentiated tissue only. The cortex, on the contrary, is the whole pre-natal adrenal, which at birth is one-third the size of the kidney. Shortly after birth the foetal adrenal cortex begins to involute, being gradually replaced (the process is not complete until the end of the third year of life) by a permanent cortex and medulla. (In my opinion this period of the switch over from the old cortex to the new is a potentially dangerous period in the life of the human infant, a too rapid involution of the foetal cortex and a too slow development of the 'permanent' cortex may constitute a hiatus in adequate cortical function which leads to severe symptoms or death.)

Although some variation exists in the cellular arrangement of the cortex in different species a more or less general pattern is present according to which the cortex is divided into three zones: the glomerulosa, the fasciculata and the reticularis. The first named is the layer immediately beneath the capsule. Time will not permit a more detailed description of the anatomy and histology of the adrenal gland.

The Medulla

The function of the adrenal medulla has been the subject of much study and speculation since Oliver and Schafer first directed attention in 1894 to the remarkable rise in blood pressure which follows the subcutaneous injection of a medullary extract. To-day the pharmacodynamic effects of adrenaline are well known but little has been definitely proved in regard to the medulla's normal physiological function. Whatever that function may be it certainly is not an indispensable factor in animal biochemistry, because the adrenalectomized animal can be maintained indefinitely in good health with a normal func-

tion provided an optimum amount of a potent cortical extract be daily injected or ingested. At post mortem examination there is seldom any hypertrophy of accessory chromaffin bodies if such be present.

The Cortex

Since investigators have failed to demonstrate any essential function of the adrenal medulla interest has gradually shifted to the cortex, as it appears to be the really important and essential part of the adrenal gland. The indispensability of the cortex in the maintenance of the functional integrity of the organism has been conclusively and absolutely proved in oft repeated adrenalectomies in animals and by clinical experience in cases of Addison's disease and established cases of adrenal haemorrhage. There cannot now be any doubt that the cortical cells of the adrenal gland elaborate a secretion, or secretions, of vital necessity to the continuity of life.

The mechanism by which this hormone exerts its effect is still unproved. However, a great advance in the study of cortical function has been made by the discovery of methods of extraction of the hormone or hormones, in sufficiently pure and potent form to permit their application to experimental and clinical research. Research into the effects of adrenalectomy on laboratory animals has done much to suggest rational hypotheses in answer to the question of cortico-adrenal function.

Chronic Adrenal Insufficiency

As early as 1856 Brown Séquard, inspired by Addison's classical description of the clinical picture of chronic adrenal insufficiency (Addison's disease), attempted to reproduce the Addisonian syndrome in animals. The rapidly fatal outcome, the animals surviving only a matter of hours, led him to conclude that the adrenals were indispensable to life. In recent years it has been frequently demonstrated that, with good surgical technique and an operation in two stages, complete adrenalectomy can be performed on all the common laboratory animals with recovery from the usually immediate lethal effects of the operation. However, in two, three, or four days dogs show the early signs of cortical insufficiency, and unless they are supplied with potent cortical hormone (cortin) they die in six or seven days. Recently it has been shown that the ingestion of large quantities of sodium chloride will prolong the life of the adrenalectomized animal.

When a two stage adrenalectomy has been completed on a dog and the animal recovers from the effects of the anaesthetic and the surgical procedure, one notices few or no abnormal signs for several days, the length of this symptom free period varying to a considerable extent with the animal's diet. Such an adrenalectomized animal like Dragstedt's thyroparathyroidectomized dogs (Dragstedt 1923) is very vulnerable to a meat diet and its post-operative life can be markedly shortened by such a meat rich diet.

The first unusual signs seen in the adrenalectomized dog are anorexia and listlessness. The animal becomes more apathetic and vomits a great deal. Usually diarrhoea is present which soon is very bloody. Muscular movements become slow and uncertain and weakness of the hind legs may cause the gait to be very unsteady. Eventually the animal lies prostrate. As insufficiency progresses the body temperature falls in warm blooded animals and the skin becomes cold and the mucosae turn pale. Muscular twitches or convulsions may appear. Respiration is first rapid and then slow. There is a terminal anuria. Death

* Read before a meeting of the O. or Soc.

occurs in coma, usually with respiratory failure while the heart is still feebly beating (Grollman, 1936). These objective signs of acute cortico-adrenal insufficiency are summarized graphically in Fig 1.

Marked anhydramia is a constant and striking feature of these adrenalectomized animals, and is due to the great loss of water and sodium chloride by way of the kidneys, owing possibly to impaired powers of resorption in the kidney tubules. This loss of water and electrolytes from the tissues and blood is such a marked feature of acute cortical insufficiency that some observers consider that the

FIG 1

FIG 2

prime function of the adrenal cortex is the maintenance of salt and water balance. It is certainly true that the quantity of cortin necessary to maintain life in an adrenalectomized animal or in a person with Addison's disease can be materially decreased by simply increasing the sodium chloride intake. In acute cortical insufficiency there is inevitably a pronounced and constant change in blood chemistry. A rise in non protein nitrogen occurs early. Later there is a rise in cholesterol and potassium* and a fall in chlorides sodium, and glucose. The pH is that of a severe acidosis. These outstanding features of the blood chemistry are graphically represented in Fig 2.

* Recent work by Zwemer would indicate that inefficient potassium elimination is a potent factor in the origin of the classical signs of acute cortico-adrenal insufficiency.

Anatomical Changes Found Post Mortem

In comparison with the severity of the *in vivo* signs of acute cortico adrenal insufficiency few anatomical changes are found on post-mortem examination. The most constant of these findings are (Banting and Cairns, 1926) (1) an enlarged thymus gland, (2) enlarged mesenteric lymphatic glands, (3) degeneration and necrosis of the liver, (4) degenerative changes in the kidneys, (5) congestion and ulceration of the gastro intestinal tract. When a chronic or partial cortico-adrenal insufficiency is produced in dogs after the method of Crowe and Wislowski (1914) only the following findings were noted after the accidental or deliberate death of the dogs: (1) enlargement of the thymus gland, (2) enlargement of the mesenteric lymphatic glands, (3) hypertrophy of Peyer's patches, (4) visible tonsils (a rarity in a dog).

(It surely must be more than a coincidence that the above findings are the most constant and diagnostic found in infants in Vancouver who have died suddenly and for no apparent reason. In these cases—and there is on the average one a month in this city—the pathologist's diagnosis is invariably 'status lymphaticus'.)

Function of the Adrenal Cortex

The question naturally arises: What is the function of the adrenal cortex? While many aspects of cortical function are still obscure, experimental research during the past decade has thrown much light on this vital and hitherto little understood endocrine gland. The cortex constitutes the whole adrenal gland in foetal life. The fact that at birth it is one-third the size of the kidney (the adult cortex being one-fortieth) is an indication of its importance in the pre-natal development of the child. Just what that role is we can at present only surmise. At birth the foetal type of cortex (and it is histologically different from the post-natal cortex) begins to involute and the new cortex and medulla to develop. The post-natal development of the cortex is not complete until the end of the third year, according to Grollman. The question of the function of the "permanent" adrenal cortex is now our immediate concern.

Out of the extensive experimentation of the past decade there emerges evidence which suggests that the chief functions of the adrenal cortex are threefold:

- 1 To maintain normal blood volume by control of excretion and resorption (in the kidney tubules) of electrolytes and water.
- 2 To act as a general tissue and cell catalyst, particularly in regard to hepatic function.
- 3 To play an important part in carbohydrate metabolism particularly in respect to glycogenesis.

There is also considerable evidence to indicate that the adrenal cortex is closely related to urea formation to vitamin C storage to cholesterol metabolism, and to resistance to infection and toxæmia. Some observers believe that it is a factor in the normal healing of wounds and callus formation. Possibly it increases the production of leucocytes and heightens their phagocytic activity.

From the mere point of view of mathematical probability it is entirely reasonable to assume that many clinical syndromes whose aetiology is at present unknown are due to cortico-adrenal dysfunction or may be influenced favourably by increased cortico-adrenal function or the presence of cortin in increased quantities. In view of the freely admitted limitations of post-mortem study of the adrenals (due to rapid autolysis) it would seem that the

effective elucidation and recognition of new clinical forms of cortico-adrenal hypofunction must be initiated and controlled by open minded clinicians imbued with the spirit of clinical research so well exemplified by the distinguished career of the late Sir James Mackenzie and so well described by Sir Thomas Lewis (1930)

Subjects for Research

In this spirit of clinical research may I suggest that the members of the Osler Society give their open minded and earnest consideration to the following entities as worthy of the clinical trial of cortico-adrenal therapy

- I The so-called thymic syndrome (status lymphaticus)
- II Cyclic vomiting.
- III Infantile diarrhoea of uncertain aetiology
- IV The vomiting of pregnancy
- V Severe infections
- VI Severe burns

I The "Thymic Syndrome"

Paediatricians practising in the Pacific North-West are well aware of the existence of a real clinical syndrome of uncertain aetiology which, like the Angel of Death, may cause the death of apparently healthy infants as they lie in their cribs presumably asleep. Post mortem examination in these cases (I quote from the data available from a series of forty-seven such unexpected fatalities in Vancouver in the eight-year period from January, 1925, to October, 1932) reveals little anatomical pathology. Usually the thymus gland is enlarged to a varying degree (assuming the normal maximum weight of this gland in Vancouver children to be similar to that found by Anderson and Cameron (1927) in Glasgow—namely, 15 grammes). The mesenteric lymphatic glands are almost invariably enlarged (tuberculosis being excluded). Petechial haemorrhages are often seen in the serous membranes of the heart and lungs. Peyer's patches are usually enlarged. In such cases the diagnosis of our pathologists (Drs A W Hunter and H. H Pitts) is invariably status lymphaticus.

In 1931, before the International Congress of Anaesthetists in New York, and a year or so later before the Vancouver Medical Association, 1933, I presented data in support of the hypothesis that these infants die because of an acute exacerbation of a temporary cortico-adrenal insufficiency, possibly predisposed by thyroid hypofunction. Time will not permit even a summary of these data here. Suffice it to say that the passage of time and the clinical trials of this therapy by my colleague Dr R P Kinsman have made me still more confident of the soundness of the original hypothesis. In brief, I believe that time and repeated therapeutic trials will eventually demonstrate that status lymphaticus and the so-called "thymic syndrome" are essentially the same being an endocrinopathy primarily involving the adrenal cortex. The final proof (or disproof) of this hypothesis (or some other yet to be formulated) is the responsibility of paediatricians who from time to time are called to treat patients for attacks of this mysterious and often fatal syndrome. The attacks referred to are often termed breath holding spells and are generally accepted as evidence of the presence of the thymic syndrome. In my opinion these syndromes are clinical manifestations of status lymphaticus differing only in degree from the tragic cases of sudden death referred to in the opening paragraph. These little patients should be given both for clinical research and for therapeutic purposes cortical extract in appropriate dosage. Dr R P Kinsman has found 14 grains of Armour's desiccated extract an effective daily dose. Certainly one need have

no fear of giving too much. If, as I hopefully expect, this therapy proves valuable, then real progress will have been made in the elucidation of one of the most tragic and puzzling problems of Pacific North-West medicine. Inasmuch as status lymphaticus snuffs out life in its early stages it is possibly of greater importance than the more widely published problems of tuberculosis and carcinoma.

II Cyclic Vomiting

I am indebted to Dr Frederic Fenger of Chicago for the suggestion that cyclic vomiting may possibly be related to adrenal cortical function. The usual teaching in regard to this well known clinical paediatric problem has been to the effect that the causative factor is ketonaemia due to incomplete oxidation of the fatty elements in the child's diet. The praiseworthy clinical researches of Dods (1935) have definitely shown that ketonaemia and ketonuria are concomitant phenomena and not aetiological factors in cyclic vomiting. The real cause still remains obscure. However, the prodromal symptoms of languor (even prostration), headache, and pallor which precede the vomiting attack, and the vomiting itself which features the syndrome, all indicate a severe metabolic disturbance that suggests cortico adrenal insufficiency as the most likely basic endocrinopathy. The adequate therapeutic use of a potent liquid extract of the adrenal cortex would do no harm and might prove valuable.

III Infantile Diarrhoea of Uncertain Aetiology

Severe diarrhoea is an invariable sequel of complete adrenalectomy in dogs. May it not be possible that in some cases of diarrhoea in infants insufficiency of cortico-adrenal function may be the aetiological factor?

IV The Vomiting of Pregnancy

In suggesting the use of adrenal cortex therapy for this universally common clinical entity, so common that some consider it "physiological," I feel that here at least I am on firm ground. With the co-operation of Vancouver colleagues, in general practice and specializing in obstetrics, I recently (1934) reviewed 200 consecutive cases of hyperemesis gravidarum that had been treated with adrenal cortex, with undoubted success in 85 per cent of cases. This series is of interest also for the reason that it shows that the oral use of adrenal cortex is effective.

V Severe Infections

As Grollman (1936a) points out, in patients who have died as a result of a severe acute bacterial toxæmia focal necroses have often been observed in the adrenal cortices. Cloudy swelling and oedema of the cortical cells, congestion and small focal haemorrhages are also common findings. The question arises, To what extent are the symptoms of asthenia, anorexia, vomiting etc., that characterize the course of the clinical condition, and which we account for by 'toxæmia,' the results of the coexisting cortical insufficiency? It is well known that adrenal ectomized animals are much more vulnerable to toxins of all kinds than are their litter mate controls. Accordingly it is reasonable to postulate for purposes of clinical research that the fatal outcome in cases of severe bacterial infection is probably due in part at least to acute adrenal insufficiency caused by the bacterial toxæmia.

VI Severe Burns

According to Grollman (1936b) in uncomplicated cases of superficial burns characteristic changes occur in the

adrenals They become swollen and deep red On section extensive haemorrhages may be found The cells are pale and swollen, and are in a process of hydropic degeneration While it is now generally supposed that the absorption of toxins from the injured skin (histamine shock) is the prime factor in the fatal outcome, the marked pathological changes found in the adrenal cortices suggest that acute cortico adrenal insufficiency (secondary to the above mentioned pathological changes in the cortex) plays a prominent part in these deaths It is quite within the bounds of reason to expect that the generous administration of cortin in such cases would prevent an otherwise inevitable fatality

Summary

In summary may I recall to you that we have briefly reviewed the probable functions of the adrenal cortex (it being the 'vital' part of the adrenal gland), and have suggested the use of a potent cortical extract in certain clinical entities, including the so called "thymic syndrome, cyclic vomiting certain cases of infantile diarrhoea, the vomiting of pregnancy, severe infections, and severe burns May I suggest in conclusion that it is only by applying clinically the findings of the experimental physiologist that real progress can be made in the solution of our medical problems Such experimental clinical research can readily be made compatible with the best interests of the patient

A congress of the International Union for the Study of Population Problems will be held in Paris from July 28 to 31 under the presidency of Professor Adolphe Landry A large number of papers will be read upon a diversity of populational, biometric, and demographic subjects A 50 per cent reduction on the French railways to and from Paris will be accorded to members attending and their families, with free entrance to the Paris Exhibition during the Congress The British National Committee of the Union is the British Population Society, founded in 1928 to develop in Great Britain and Northern Ireland scientific studies pertaining to problems of population Membership of this society is open to all those whose scientific or other special qualification will enable them to forward the objects of the society, and carries with it membership of the International Population Union with the right to attend and speak at meetings of the Union and to contribute papers upon populational subjects Associate membership is open to all interested in populational problems and includes the right to attend the International Congress The official journal of the Union is *Population* Full particulars of the British Population Society may be obtained from the hon secretary Dr C Conyers Morrell, D P H., Mudeford House, Mudeford Christchurch Hants

CHRONIC AGRANULOCYTOSIS SUCCESSFULLY TREATED WITH LIVER

By

C R DAS GUPTA, M B., D T M Calcutta

AND

L J WITTS, M D Manch, F R C P

(From the Medical Professorial Unit St Bartholomew's Hospital London)

A pastrycook aged 25 was admitted to St Bartholomew's Hospital on May 22, 1936, for dimness of vision He was quite well and healthy, with normal eyesight, till five years before, when his eyes became inflamed and his vision impaired He was partially relieved of symptoms for the time being by hospital treatment, but attacks recurred and alternated with intervals of relief Both eyes were affected by chronic iridocyclitis, of which investigation failed to reveal the cause In the course of these investigations he was found to have a very low white blood count It was naturally wondered whether the leucopenia was in any way connected with the iridocyclitis, its origin or its treatment, and whether restoration of the white count to normal would improve the condition of the eyes

Case History

Apart from the iridocyclitis the only abnormality was a shallow ulcer on the inner aspect of the cheek The ulcer was first noticed by the patient about nine months before, and it appeared and disappeared at irregular intervals without any treatment The family and personal history were good and there was no history of allergy in the patient or his relatives Nine months ago he took a proprietary tonic which then contained amidopyrine of which he probably had some 30 grains in all About the same time he had one or more injections of gold for the eyes without any benefit.

The blood count on May 20 1936, was red cells 6 140 000 per c.mm, haemoglobin 102 per cent platelets 250 000 white cells 3,600 of which 1 188 were polymorphonuclear cells Two days later the white blood count was 2 800 of which 812 were polymorphonuclear cells The differential count on the bone marrow obtained by sternal puncture on June 4 1936 was as follows

Myeloblasts	3%	Eosinophils	2%
Premyelocytes	3%	Lymphocytes	4%
Myelocytes	32%	Monocytes	0.5%
Metamyelocytes	10%	Reticulum cells	0.5%
Staff neutrophils	13%	Macroblasts	11%
Segmented neutrophils	1%	Erythroblasts	20%
Basophils	0%		

The most notable feature of the marrow smear is the excessive proportion of myelocytes, apparently due to a failure in their development into polymorphonuclear cells Maturation has been arrested, though at a later stage than in a previous case, in which the cells had not advanced beyond the myeloblast level (Witts 1936) The myeloid cells especially the myelocytes seemed more fragile and more easily smudged than in health, their granulation was scanty and often lacked uniformity The nucleated red cells were less mature than in the normal marrow smear and there were few pyknotic nuclei In view of the changes in the erythropoietic tissue and of the subsequent response to liver it is interesting that the fractional test meal revealed achlorhydria unfortunately the effect of histamine was not observed

Failure with Nucleotide Therapy

It was concluded that the patient was suffering from a chronic form of agranulocytosis, possibly the effect of

the amidopyrine and gold which he had received. In previous work on agranulocytosis (Witts, 1936) we had had troublesome reactions on treatment with pentnucleotide. Pentnucleotide is an approximately equimolecular mixture of the sodium salts of the four nucleotides obtained by the hydrolysis of yeast nucleic acid. These nucleotides are all compounds of bases with *d*-ribose and phosphoric acid. The four nucleotides are adenylic acid (adenine ribo-phosphoric acid), guanylic acid (guanine ribo-phosphoric acid), uridylic acid (uracil ribo-phosphoric acid), and cytidylic acid (cytosine ribo-phosphoric acid). Of these nucleotides the first two are derived from purine bases and the second two from pyrimidine bases. Dr A. L. Bacharach suggested to us that, in view of the pharmacological action of adenosine on the cardiovascular system, it was possible that the adenylic acid was responsible for the reactions occurring after injection of pentnucleotide and that they might be avoided by omitting the purine derivatives. The Glaxo Laboratories kindly supplied us with an equimolecular mixture of the two pyrimidine nucleotides, cytidylic and uridylic acids. It was put up in the same concentration as pentnucleotide, 0.7 gramme per 10 c.c.m. Ten cubic centimetres were injected twice daily for six days, but there was little effect on the total or the differential white cell count. After a few days' interval the patient was treated with pentnucleotide in doses of 10 c.c.m. twice daily intramuscularly for nine days, this too failed to produce any increase in the white count or the polymorphonuclear cells. Neither the pyrimidine nucleotides nor pentnucleotides gave any troublesome reactions in this patient.

Results of Liver Treatment

Nucleotide therapy having failed, the patient was treated with liver extract (hepatex), which was given in doses of 2 c.c.m. twice daily intramuscularly. An improvement in

treatment, though it was still below the normal limit, and large mononuclear cells, which had constituted about 20 per cent of the white cells, fell to about 6 per cent at the end of the treatment. The total white cells, neutrophils, and weighted mean are shown graphically in the chart. Sternal puncture was done again at the end of liver treatment, when a preponderance of polymorphonuclear leucocytes was found and the differential count was as follows:

Myeloblasts	4%	Eosinophils	1%
Premyelocytes	2%	Lymphocytes	10%
Myelocytes	11%	Monocytes	0.5%
Metamyelocytes	6%	Reticulum cells	0.5%
Stiff neutrophils	35%	Macroblasts	3%
Segmented neutrophils	14%	Erythroblasts	12%
Basophils	0%		

From the examination of the blood and of the sternal puncture material the patient now appeared to be in a normal haematological state, but his dimness of vision persisted. It was decided, by giving a therapeutic dose, to find out if he was susceptible to amidopyrine. With this view the diurnal variation of the leucocytes from 10 a.m. to 6 p.m. was first observed, the patient being kept in bed during the whole time but having the usual diet. Next the effect of a single dose of amidopyrine and of three successive doses of the drug were noted. No immediate effect on the total white cells and the neutrophils was apparent after single or repeated doses, though there was a suggestion of a slight delayed action. As the patient had had injections of gold for his eye trouble the effect of 0.1 gramme of solganol intramuscularly was noted. The white cells fell from an unusually high level of 9,200 (neutrophils 6,800) to a minimum of 5,000 (neutrophils 2,000) six hours later, and they remained at a lower level than previously for the remainder of the period of observation. It is doubtful, however, whether

the total white cell count and the neutrophils was noticed on the fifth day. This improvement continued and reached a maximum on the thirteenth day of the liver treatment when the total white cells had risen from 3,800 to over 7,000 per c.m.m., of which more than 5,000 were neutrophils. Liver treatment was continued for thirty-five days during which time the total white cells fluctuated between 6,000 and 7,000 per c.m.m., with a total neutrophil count of 4,000 to 5,000 per c.m.m. The weighted mean of the nuclear lobes in the Arneith count which was very low to start with was much higher at the end of the liver

treatment, though it was still below the normal limit, and large mononuclear cells, which had constituted about 20 per cent of the white cells, fell to about 6 per cent at the end of the treatment. The total white cells, neutrophils, and weighted mean are shown graphically in the chart. Sternal puncture was done again at the end of liver treatment, when a preponderance of polymorphonuclear leucocytes was found and the differential count was as follows:

He was seen again in May 1937. He was much better in himself but there was no change in the eyes and the iritis continued to flare up at intervals. He had had

no treatment except atropine drops. The blood had been examined several times and found normal. The count on May 4, 1937 was red cells, 4,940,000 per c.mm., haemoglobin, 110 per cent., white cells, 7,100 per c.mm., colour index 1.1. The differential white count was lymphocytes 14 per cent., polymorphs 77 per cent., eosinophils 1 per cent., basophils 1 per cent., metamyelocytes 2 per cent., and monocytes 5 per cent.

We do not know why some patients with agranulocytosis respond to nucleotide, others to liver, and others again to neither of these substances. In acute cases, most of which are due to sensitivity to amidopyrine, the predominant cell in the marrow is the myeloblast or stem cell. It is in cases of this kind that nucleotide has had most success. Our patient's illness was chronic, and the development of his white cells was apparently arrested at the myelocyte level. He responded to liver but not to nucleotide. It may be, then, that the results of treatment are to some extent determined by the level at which leucopoiesis is arrested, but our data on these matters are still too fragmentary to be regarded as reliable evidence.

Summary

A man who had suffered for five years from an unexplained iridocyclitis was discovered during the course of a routine investigation to have a mild chronic agranulocytosis. Sternal puncture revealed arrest of maturation of the myelocytes in the bone marrow. The patient had taken amidopyrine and gold in the past, but no clear evidence of sensitivity to either of these drugs was obtained. There was no response to pyrimidine nucleotides or to pentnucleotide, but on treatment with intramuscular liver extract the white cells returned to normal levels and the bone marrow was restored to normal. The blood has remained normal without further treatment, but the iridocyclitis has not greatly improved.

REFERENCE

Witts L. J. (1936) *Proc. roy. Soc. Med.* 29 671

L. J. Lindström (*Finska Läk.Sällsk. Handl.* March, 1937, p. 207) calculates that from 2 to 3 per cent. of all males suffer from undescended testicle, and that at least thirty different operations have been devised for its cure. At the Vasa Hospital he has practised the operation devised by the American Torek on seven patients whose ages ranged from 1½ to 33 years. One of the patients, aged 22, was so pleased with the results of the first stage of the operation that he refused the second stage as superfluous. In every case the wounds healed by first intention, the testicle remained within the scrotum, and the patient was very pleased with the final results. At the first stage of the operation the testicle is detached from the surrounding structures, the cord being freed from fibres of muscle and connective tissue and the pampiniform plexus. After the testicle and scrotum have been secured to the inner side of the thigh the second stage of the operation is undertaken from four to six months later, and the testicle and scrotum are secured in the normal position. For children it may be well to give hormone treatment as a preliminary to the operation, which should preferably be undertaken at the age of 12 to 14 if a hernia or other complication has not required an earlier intervention. Waiting till puberty may render any operation superfluous, and in this connexion the author refers to the experience of Bjerke, who in 1935 gave an account of 188 Danish boys with undescended testicle. In 63 per cent. spontaneous descent occurred the arrival of the testicle within the scrotum taking place in most cases between the ages of 10 and 15.

CANCER OF OESOPHAGUS TREATED BY DEEP X-RAY THERAPY

(SYMPTOM FREE NEARLY TWO YEARS)

BY

HERBERT TILLEY, F.R.C.S.

Consulting Surgeon Ear, Nose and Throat Department
University College Hospital and the Radium
Institute

This brief communication refers to a patient in whom cancer had developed in the mid-thoracic region of the oesophagus. The case-history seems worthy of publication because the method employed by Dr Levitt (*vide infra*) for distal irradiation of the lesion was followed by a much longer freedom from recurrence than had hitherto come within my personal experience. This had been limited to local therapy, which during the past ten years or so involved the implantation of platinum-screened needles containing radium element or its emanations in glass "seeds".

It is scarcely necessary to add that, by direct oesophagoscopy, these were inserted into the visible growing margins of the lesion and its deeper peripheral extensions in so far as these could be gauged by careful inspection of the diagnostic x-ray film. Perhaps it may be permitted me to state that having been associated with the Radium Institute since its foundation in 1910, an exceptional amount of material has been at my disposal for testing various techniques which, each and all, have aimed at providing uniform and efficient irradiation of oesophageal cancer. Yet in spite of such advantages the results have been very disappointing. I cannot recall to mind a single patient who did not succumb to the disease within twelve months from the commencement of treatment.

In making this statement it would be only fair to add that a large majority of those patients belonged to the poorer classes and did not seek relief from their chief symptom, dysphagia, until the primary lesion was far advanced and not infrequently associated with near or distant secondary deposits. In such circumstances it was only possible to destroy the obstructive portion of growth and thereby restore the power of swallowing. As might be expected, considerably longer respites were afforded to patients more happily situated provided that their lesion was treated in its earlier phases. But even so, I think it will generally be agreed by experts that luck has played a considerable part when a patient has enjoyed a comparatively long freedom from recurrence, because this implies that, by mental visualization alone, the surgeon has been fortunate enough to implant the radium needles in the deeper, peripheral, and actively growing areas of the growth (*vide H. S. Souttar, British Medical Journal* May 1, 1937). On the other hand, it cannot be denied that those who have mastered the technique of local irradiation will secure better results than the occasional operator—which seems to support the definition of "luck" as an accident which rarely happens except to the competent.

Be that as it may, I had seen a few patients who, after treatment by deep x-ray therapy, had secured far longer periods of freedom from recurrence than any obtained by me with local irradiation, and the following case-history seems to warrant the advice which was given to the patient.

Clinical Record

H. S., aged 75, was referred to me on July 7, 1934, with the history of "difficulty in swallowing," which had been slowly increasing since it was first noticed some three

months earlier. Otherwise he was a well built, healthy-looking man who appeared to be much younger than his years. A medium sized oesophageal bougie met with complete obstruction about four or five inches below the cricoid constriction. The patient was referred forthwith to Dr Walter Levitt with the expressed wish that he should treat the case by deep x-ray therapy provided that my provisional diagnosis of a malignant lesion was confirmed by x-ray examination of the strictured region. He sent the patient to Dr John Sparks, who returned a "true bill" within a few hours, and thenceforward Dr Levitt took charge of the case. It may be of interest to those engaged in radiotherapeutics to read the following description of and comments on the method he adopted, together with other details which should be of value to surgeons who are practically concerned with cancer of the oesophagus.

Notes by Dr Walter M Levitt

The Method—(1) The rays are entered through long narrow fields centred over the oesophagus—long because of the tendency of the disease to spread submucously up and down the oesophagus and narrow in order to limit the irradiation of normal tissues. (2) Usually six fields are employed, and these are grouped about the mid line, three anteriorly and three posteriorly. A geometric method of planning them is used in order to ensure accuracy of firing. (3) The treatment is applied daily for about a month. (4) The technical details of the treatment are so adjusted that a certain minimum intensity ("brightness of illumination") is obtained at the growth, and a certain daily dosage. (5) Severe skin reactions which arise as a result of giving the requisite dosage invariably clear up rapidly and without any difficulty.

Results—A good palliative result is obtained in a high proportion of cases—over 60 per cent. The growth apparently disappears and swallowing is restored. The ultimate prognosis, however, varies in the different sections of the oesophagus. The best situation is the upper third of the oesophagus. One patient with a carcinoma in this region is alive and well three and a half years after treatment and another three years after treatment. It seems likely that a certain number of permanent cures may be obtained in this region. The middle third growths do very well for a time, perhaps a year or two but so far no patient has survived longer than two and a half years. The lower third growths give the worst results, as to both immediate result and duration. Growths originating in the cardia of the stomach and invading the oesophagus should not be treated.

Complications—The two most common are mediastinitis and lung changes. Mediastinitis results when an extensive infiltrating growth is rapidly absorbed leaving the oesophageal wall porous to the oesophageal contents, thereby allowing the mediastinum to be infected. This is not a common complication. Lung changes, although their incidence has been reduced, still occur in a proportion of cases especially in the middle third growths and they vary in severity. If the patient survives long enough they tend to improve but at any stage the patient may succumb to an ordinary acute respiratory infection.

In Mr S's case the treatment was applied from July 9 to August 28 1934 and it will be remembered that the lowest portion of his stricture always showed a suspicious roughness after the treatment. I cannot help feeling that I did not carry my fields down as low as I ought to have done if I had the result might have been better.

Subsequent History

On September 18 and November 29 1934 Dr Levitt reported that there was "no sign of any growth and food was being swallowed without any difficulty. This satisfactory condition was maintained for approximately eighteen months when the patient again began to notice

a slight obstruction to the passage of 'stringy foods and the skins of certain fruits'. On May 6, 1936, under a general anaesthetic and by direct oesophagoscopy, I found that the upper end of the original ulceration was represented by a dull white ring of scar tissue through which it was only possible to pass a No 14 bougie, and this met with a second constriction about two inches further down. It was soon found that if the bougie was passed through both of these and left *in situ* for five minutes semi solid food could be swallowed without difficulty. The patient quickly learned to carry out the manipulations without assistance. Nevertheless it was impossible not to regard seriously the recurrence of some degree of dysphagia, however much one hoped it might be due to a later development of scar tissue in the lumen of the original growth. But had there been any doubt as to its recrudescence this was soon dispelled by the supervention of hoarseness, which on September 17 last I found to be caused by "recurrent paralysis" of the left vocal cord, and obviously implied a mediastinal extension of the oesophageal growth.

Thenceforward difficulty in swallowing increased rapidly, and finally liquid nourishment was in great part regurgitated. Consequently on December 14 I inserted a Symonds gum-elastic tube, which afforded an easy passage for fluid nutriment. It remained *in situ* for three weeks, by which time maceration had brought about its collapse and therefore an almost complete inability to swallow liquids. On January 5, 1937, a fresh tube was inserted, and this sufficed the needs of the patient until March 21, when he died in his sleep.

Comment

The dates given in the above case-history show that from the completion of the treatment the patient lived four months short of three years. During that time he was entirely symptom free for a year and eight months, and for the following eight months there was little difficulty in swallowing soft foods after the passage of a No 14 oesophageal bougie. Furthermore, until the late autumn of last year the patient was able to enjoy all the amenities of his country life, which included riding and shooting. None of my previous early cases treated by local irradiation had lived more than fifteen months, and few reached the anniversary of such intervention. Nor am I aware of any records which prove that other surgeons have secured more favourable results. Had the case above reported been so exceptional as to merit the criticism that "one swallow does not make a summer" I should have hesitated to draw any deductions from my solitary harbinger, but seeing that Dr Levitt (*vide supra*) had been able to prove the existence of others, I feel tempted to believe that the winter of our discontent with local irradiation of oesophageal cancer has been made brighter by what is termed deep x ray therapy.

A Hagedoorn (*Brit J Ophthal* May, 1937, p 234) describes the changes occurring in a woman of 56 years who had been under treatment for trachoma since childhood. Several photomicrographs minutely described illustrate the paper. After two years treatment the eye and posterior parts of the lids were excised. On examination sections indicated a precancerous condition. One year later a small recurrent tumour appeared confirming the diagnosis of cancer though no other metastases were discovered. Only one case of cancer associated with trachoma has been previously recorded.

ORAL ADMINISTRATION OF OESTRIN TO PREMATURE BABIES

BY

MABEL F POTTER, M.B., Ch B., M.C.O.G.

Obstetric Registrar Bristol Royal Infirmary Honorary
Medical Officer Bristol Maternity Hospital

*The premature infant has a very precarious hold on life, and the neonatal mortality of these babies is high. Therefore any treatment likely to reduce this loss will be eagerly received by both obstetricians and paediatricians.

In an article in the *Archives of Disease in Childhood* Moncrieff (1936) gives the results of an investigation at Queen Charlotte's Hospital into the use of subcutaneous injections of oestrin for premature babies, in this he reports that Aschheim (1927) suggested that premature babies might be benefited by the administration of oestrin. The arguments in favour, according to Martin (1929) are

- 1 The blood of newly born babies contains a comparatively large amount of oestrin
- 2 This is rapidly excreted by the kidney, and the urine is oestrin-free after about four days
- 3 A baby born prematurely is at a disadvantage because it lacks the stimulus of the oestrin which would normally have been present in its blood had it remained *in utero*
- 4 The administration of oestrin helps to make up this deficiency

Moncrieff gives a résumé from the literature of previous experience with oestrin and then adds the results of his own investigations. His conclusions, based on the results with eighty premature babies, some treated and some as controls, were that 'subcutaneous injections of oestrin during the first seven days of life have a slight stimulant effect as indicated by a better gain in weight than in babies not so treated. This improvement is more obvious in girl babies than in boy babies.' Moncrieff does not consider the advantage definite enough to justify the use of oestrin as a routine treatment, however.

Since about September, 1936, oestrin has been used orally for premature infants at the Bristol Maternity Hospital. In personal experiments in feeding mice with oestrin it was found to act as well given orally as when injected, although a larger dose was necessary. Therefore it was decided to give the babies an oral preparation to avoid the unnecessary trauma of daily or more frequent injections, and Schering's preparation of progynon dragées was selected for use. Lately these have been supplied free by Messrs Schering Ltd.

The dose decided upon and found satisfactory was half a dragée twice daily. This is equivalent to 500 international units twice daily. One dragée was dissolved in two drachms of warm (not hot) water and one drachm given as a dose. At first the oestrin was given with little faith in its efficacy, but the nursing staff soon reported that the premature babies were causing less anxiety, the initial loss of weight appeared to be less, and this was usually made up sooner. These babies were very carefully tended but only under the same conditions as could be obtained in any ordinary home.

Since using oestrin no premature baby born at this hospital to whom it was administered has died, a number of the babies were under 4 lb at birth and all have been born during the coldest six months of the year.

Therefore, although the series was only a small one, it seemed to be worthy of record.

Before giving details of the premature babies it might prove of interest to mention one sick infant, a boy, who appeared to be benefited by progynon. In this case the maternal history revealed the presence of toxæmia, albumin ++, and marked oedema, the blood pressure was 168/110. Medical induction took place on November 23, 1936, at thirty-nine weeks. The baby weighed 7 lb at birth, and, the mother having no breast secretion, was artificially fed, he developed gastro-enteritis. His weight fell to 4 lb 14 oz at 2 weeks, and he was very ill. At this stage, his weight being under 5 lb, it was decided to add progynon to the other treatment, and this appeared to help. The baby eventually did well, gaining 1/2 lb weekly and weighing 12½ lb at 4½ months.

Two premature babies not born in the Bristol Maternity Hospital are included in the following series as they were born during the period under review and received the progynon treatment.

Case Histories

Cases 1 and 2—Premature girl twins. The mother had albuminuria, hydramnios and oedema of legs. The first baby weighed 4 lb 7½ oz. at birth and 4 lb 7½ oz. at 2 weeks, and the second baby 3 lb 10 oz. at birth and 3 lb 10½ oz. at 2 weeks. Both did well and were discharged at 2 weeks.

Case 3—Baby girl born September 9, 1936, at thirty-five weeks of healthy parents. Weight 3 lb 12 oz. There was a large swelling of the head below the occiput and extending downwards into the neck. The swelling was mostly cystic with a small portion more solid. The skin was deficient over this swelling. Operation was performed at twenty-four hours, a meningocele and a small encephalocele being removed with redundant skin, etc. and the healthy skin sutured. The patient was feeble at first, but always took feeds well. She was discharged at 4 weeks, 3 lb 14 oz. in weight. At 6 months she weighed 11 lb and seemed normal in every way.

Case 4—Baby girl. Third pregnancy, Terminated November 23, 1936. Maternal history: first baby premature, lived one week; second baby normal, but pre-eclampsia present during the pregnancy. No evidence of toxæmia but labour started spontaneously at thirty-three weeks. Baby 3 lb 12 oz. at birth. She lost weight for over a week, but gained 1 oz. daily for last four days and was discharged at 2 weeks, weighing 3 lb 10 oz.

Case 5—Baby girl. Maternal history: toxæmia, albuminuria + oedema + blood pressure 190/90. Medical induction took place at thirty-eight weeks on November 19, 1936. The infant weighed 4½ lb at birth and 5 lb at 2 weeks.

Case 6—Baby boy. Maternal history: chronic nephritis two previous miscarriages. The mother had been on diet and treatment throughout pregnancy but had become very toxic, blood pressure 210/144, oedema +, albuminuria ++. Surgical induction on February 3, 1937, at thirty-three weeks, weight of baby at birth, 3 lb 13 oz. at 18 days 4 lb 1 oz.

Case 7—Baby girl. Maternal history: mother pre-eclamptic, blood pressure 176/110, oedema +, albuminuria ++, no improvement with treatment. Medical induction performed on February 8, 1937, at thirty-six weeks. Weight at birth, 3 lb 8 oz. Patient discharged at 17 days weighing 4 lb 2½ oz.

Cases 8 and 9—Twins (monovular girls). Maternal history: mother 36 years old, this being her second pregnancy, there was toxæmia, albuminuria + oedema ++, and the blood pressure was 160/110. Case 8 weighed at birth 4 lb 7½ oz., and at two weeks 4 lb 12 oz. Case 9 at birth was 4 lb 1½ oz., and at 2 weeks 4 lb 7½ oz. The weights at 3 weeks were Case 8 5 lb., and Case 9 4 lb 13 oz.

Case 10—Baby boy. Maternal history: the mother was 36 years old, and had been married ten years. This was her

first pregnancy Spontaneous labour occurred at thirty six weeks with a difficult breech delivery The baby was some what shocked and weighed 4 lb 15 oz. at birth On discharge at 2 weeks his weight was 5 lb 4 oz.

Case II—Baby boy Normal healthy parents. Spontaneous delivery at thirty five weeks. His weight was 5 lb 3½ oz. at birth 5 lb 5 oz. at 2 weeks and 8 lb 12 oz. at 2 months

Table of Results (No Deaths)

Case No	Sex	Weight		Age on Discharge
		At Birth	On Discharge	
1	Girl	4 lb 7½ oz.	4 lb 7½ oz.	2 weeks
2	"	3 lb. 10 oz.	3 lb 10½ oz.	2 "
3	"	3 lb 12 oz.	3 lb 14 oz. + operation	4 "
4	"	3 lb 12 oz.	3 lb 10 oz.	2 "
5	"	4 lb. 8 oz.	5 lb 0 oz.	2 "
6	Boy	3 lb 13 oz.	4 lb 1 oz.	2½ "
7	Girl	3 lb 8 oz.	4 lb 2½ oz.	2½ "
8	"	4 lb 7½ oz.	4 lb 12 oz.	2 "
9	"	4 lb 1½ oz.	4 lb 7½ oz.	2 "
10	Boy	4 lb 15 oz.	5 lb 4 oz.	2 "
11	"	5 lb 3½ oz.	5 lb 5 oz.	2 "

Summary

Details are given of eleven premature and one sick baby treated with progynon This preparation of oestrin, given orally, appears definitely helpful to premature infants The babies cause less anxiety The feeds are taken better, the initial loss of weight appears less and is usually made up sooner No baby to whom it was given died

R Opsahl (*Norsk Mag Laegevidensk* April 1937, p 9) has scrutinized the records of necropsies at the Ullevaal Hospital in Oslo for the twenty-year period 1916-35, with special reference to primary malignant disease of the lungs During this period 2,005 cases of carcinoma and sarcoma came to necropsy the malignant disease being in some of these cases an incidental finding In addition to the fifty six established cases of primary malignant disease of the lungs (twenty-eight men and twenty-eight women) there were fourteen cases in which this diagnosis was uncertain and eight in which it was possible but not probable The age incidence was greatest between 50 and 60 (seventeen cases)—a little earlier in life than in other forms of malignant disease which reached their maximum frequency between 60 and 70 Only in eleven of the fifty six cases were the new growths diagnosed clinically The duration of the disease was usually between four and twelve months The fifty six cases were classified in four five-year groups and in relation to the total number of cases of malignant disease in each five-year group In the first five years primary malignant disease of the lungs constituted 1.8 per cent of all the cases of malignant disease in this period The corresponding figures for the next three five-year periods were 2.7 3.1 and 3.1 respectively Putting these figures to the test of modern statistical criteria the author comes to the conclusion that his material gives no support for the assumption that there is a real increase in the incidence of primary malignant disease of the lungs.

VACCINE TREATMENT OF MEASLES

BY

A. A. CUNNINGHAM, M D Dub, M R C P Lond,
D P H

Senior Medical Officer North Western Hospital (LCC)
 late Senior Medical Officer Park Hospital (LCC)

Measles is typically a disease of childhood, the majority of the patients being attacked in the first five years of life, and although it is still regarded by the general public as a trivial illness, its complications, both immediate and remote, are severe enough to constitute a major medical problem Bronchopneumonia remains the most serious and dreaded complication, and is largely responsible for the present mortality rate

Wynn of Birmingham has for some years advocated the use of a special vaccine in the treatment of pneumonia and bronchopneumonia His results have apparently been good in those cases in which the diagnosis is made early and the appropriate vaccine treatment instituted in the first twenty-four to forty-eight hours of the illness The vaccine for bronchopneumonia contains equal numbers of pneumococci, haemolytic streptococci, and Pfeiffer's bacilli Fresh cultures are used and the organisms are killed by heat Wynn (1936) recommends 600 million organisms—that is, 200 millions of each organism—as a suitable injection dose for an adult Children require proportionately smaller doses, but at 1 year old 20 millions of each organism can be given with impunity Three such injections subcutaneously at intervals of twenty four hours are recommended

Production of Reactions

The vaccine treatment of acute infections has not found favour owing to the fear of producing reactions in a patient who is dangerously ill According to Wynn this is a fallacy, as reactions occur in chronic infections only when patients are sensitized and specific antibodies are present in the circulation In the early stage of an acute infection antibodies are absent, and therefore these reactions do not occur Immunotherapy by vaccine treatment aims at the production of antibodies at an earlier stage than would usually be the case Specific antibodies do not appear for several days, but the vaccine used is stated to have an immediate effect in that it stimulates the production of non specific antibodies—various bacterial substances which appear in the circulation These are later supplemented by the specific antibodies, but the greatest stress has been laid on the value of the non specific immediate response to the vaccine injections which if given sufficiently early are claimed to abort the infection

In measles bronchitis is present in the early stages in all but the mildest and modified cases It usually clears up in a few days, but occasionally, and especially in poorly nourished and debilitated children it progresses to bronchopneumonia The detection of bronchopneumonia is very difficult at times and it is only by taking into consideration the general condition of the patient, in conjunction with the various physical signs and symptoms, that one can hope to arrive at a reasonably accurate diagnosis Areas of lung collapse are met with in young children with acute bronchitis and may easily be mistaken for areas of pneumonic consolidation

In this investigation we decided to treat only those patients suffering from measles in the various stages of development up to the time of the appearance of the full blown morbilliform eruption All late cases with

fading rashes were therefore excluded. The question of using alternate cases on admission as controls was carefully considered, but this was regarded as impracticable, so it was decided to treat by vaccine those cases admitted to five specified wards and to treat as controls those admitted to five other wards. Admissions to the various measles wards were in strict rotation as vacancies occurred.

Treatment

The stock vaccine used was prepared in the Southern Group Laboratory under the direction of Dr J E McCartney. It was killed by heating at 60°C for thirty minutes, and was made from young active cultures. The vaccine was so constituted that there were 600 million organisms in each cubic centimetre, 0.1 ccm being regarded as a suitable dose for a child 1 year old, 0.2 ccm for a child 2 years old, and so on. The first injection was given for the most part on the day of admission but in a few instances, when the child was admitted late at night the injection was deferred until the next morning. The routine treatment consisted of three subcutaneous injections of equal amount at intervals of twenty-four hours. All cases of measles had a small prophylactic injection of diphtheria antitoxin on admission.

The following tables give briefly the incidence of the various complications in the specially treated group and in the corresponding set of controls.

TABLE I—*Chest Complications*

Series	Cases	Lobar Pneumonia	Bronchopneumonia (measles)				Bronchopneumonia (measles and pertussis)		Empyema (after)	Deaths (due to measles)		
			No.	%	Deaths	Mortality	No.	Deaths	No.	No.	%	
Vaccine	236	1	24	10.1	5	20.8	2	1	1	5	2.1	
Control	278	—	25	9.0	7	28.0	1	1	—	7	2.5	

TABLE II—*Ear Complications*

Series	Cases	Measles					Measles (with intercurrent disease)		Deaths (directly due to ear complications)
		SOM (right)	SOM (left)	SOM (bilateral)	SOM Total	Mastoidectomy	SOM (measles and pertussis)	SOM (scarlet fever)	
Vaccine	236	10	9	16	35 = 14.8	1	1	1	—
Control	278	10	15	14	39 = 14	1	1	1	—

S O M = Suppurative otitis media.

TABLE III—*Complications in Age Groups*

Age Group	Vaccine Series (236 Cases)						Control Series (278 Cases)					
	No in Group	Bronchopneumonia	Suppurative Otitis Media		Deaths		No in Group	Bronchopneumonia	Suppurative Otitis Media		Deaths	
0-2	95	15	15.8	29	21.0	4	4.2	106	16	15.1	7	16.0
2-3	53	3	5.6	9	16.9	1	1.9	67	5	7.4	7	10.4
3-4	32	1	3.1	5	15.6	—	—	43	1	2.3	2	10.0
4-5	23	3	13.0	1	4.3	—	—	31	2	6.4	3	9.7
5+	31	2	6.0	—	—	—	—	34	1	2.9	5	14.7

Discussion

In this investigation 236 patients with measles were treated with a vaccine prepared according to Wynn's formula, and a corresponding control series of 278 cases was treated on similar general routine lines without vaccine. The majority of the patients were under 5 years of age the youngest being about 9 months old. The injections were without exception innocuous, and we did not observe any general febrile reaction which could reasonably be attributed to the vaccine. Slight local reactions were seen from time to time, but were rare.

An analysis of results shows that there has been no demonstrable diminution in the incidence of the two most common complications of measles—namely, broncho pneumonia and otitis media—nor has the mortality rate been affected to any appreciable extent. Mr B E Spear of the statistical department of the London County Council, to whom I am indebted for the following report, states 'that from the statistical point of view the results justify the negative conclusion reached as to the treatment. The claims made by Wynn as to the value of the vaccine in aborting pneumonic infections and in reducing the mortality rate have not been confirmed by this investigation in young children with measles as the primary infection. It is true that the total number of patients treated was relatively small, but one feels that no useful purpose would be served by the continuance of vaccine treatment in measles with the vaccine as at present constituted.'

I wish to express my gratitude to Dr H Stanley Banks, medical superintendent of the Park Hospital (L.C.C.) for his advice and criticism and for permission to publish this paper.

Clinical Memoranda

Slimming Drugs and Cataract With Notes of a Case

During the past few years compounds of dinitrophenol have been used as metabolic stimulants in the treatment of obesity, especially in America. In 1935 Tainter, Stockton, and Cutting published results of treatment with 2,4-dinitrophenol in doses of 100 mg daily for one week, then 200 mg for several weeks with gradual increase to 300 mg., followed by reduced doses if toxic symptoms occurred, such as dyspnoea, oedema, urticarial rashes and prostration. They reported that no pathological changes were produced in the blood cholesterol, liver, or blood count in four years of treatment and weight was reduced. Koch Lee, and Tainter (1935) reported no changes in the liver or any other tissue in dogs killed by lethal doses.

In 1935 Horner, Jones, Boardman, and other authors published cases of cataract in human beings following this treatment. They found that after the first signs appeared the development was rapid. The cornea was normal, the aqueous showed a slight slit lamp flare, the anterior capsule was spotty dry and lustreless and fine grey subcapsular cloudy opacities were present. Later irregular pearl grey opacities appeared deeper in the cortex with polychromatic specular reflection from the posterior cortex. Marked swelling of the lens followed. The cause was thought to be increased permeability of the lens capsule. Secondary glaucoma sometimes occurred.

In October, 1936, Whalman, in Los Angeles, published notes of forty cases with details of twenty seven cases of cataract in obese females (average weight 200 lb) from 25 to 50 years of age. All lost considerable weight. Maturation occurred in from seven days to six months, the average being six weeks. Needling followed by linear extraction gave good results. The daily dose was from 100 mg to 500 mg., and the period of treatment varied from one to eighteen months. The cataract is always bilateral, though usually more advanced in one eye than in the other.

CASE HISTORY

On January 27, 1937 I saw a young woman aged 28, weighing 144 lb. She complained of failing sight in the left eye for a fortnight. The vision was right eye 6/12 left eye less than 6/60 not improved by glasses. The left eye showed a pearly swollen cataract with silvery sectors, and the right a fine punctate central lenticular opacity. None of the usual causes of cataract were present, and only close questioning elicited that she had been taking Messrs. Crookes' preparation "dekrasil"—that is 4,6-dinitro *o*-cresol—for three years for slimming purposes, and that it was successful in keeping the weight down. Dr. Havard told me that her original weight was 178 lb., and at one period it was reduced to 134 lb. For the first six months one capsule a day was taken and then two, with occasional intermissions of one month if tachycardia developed, or a slight yellow pigmentation of the conjunctivae. Calcium sodium iodide ointment was prescribed, and abundant fruit and vegetables rich in vitamin C, and then on Professor Dodds's kind suggestion, ascorbic acid. No improvement took place and by February 22 the right eye was blind as well. On March 3 the left eye was needled, and on March 17 a linear extraction was done. Convalescence was uneventful, and on April 2 with + 11 D sph. + 1 D cyl./45° the vision was 6/9 partly. A capsular needling may be needed later.

It is difficult to prove that these cataracts are directly due to dinitrophenol products, but though the number of women taking them is very large it seems that the proportion developing cataract is too great for mere coincidence. The absence of lenticular changes in dogs given lethal doses may indicate that the time factor is important. To prove the connexion statistically one would have to show that in females of these age classes the proportion developing cataract was greater in those taking these drugs than in the general population of obese females of these age classes. Perhaps one should limit the classes to obese females, and I do not know that such statistics are available. On the other hand one knows that, apart from congenital, diabetic, or other severe general disease and traumatic cases, cataract in young women is very rare, and I think that most ophthalmologists would agree that when it occurs it is in poorly nourished feeble individuals, resembling those suffering from prolonged lactation, and not in a stout buxom type like the present case.

It is likely that more of these cases will occur in Britain and it seems doubtful whether the use of preparations of the dinitrophenol type should be continued. Even though the results of extraction are good it is a great drawback for a young woman to be dependent on cataract glasses for life.

I have to thank Messrs. Crookes for permission to name the preparation that was employed in this case.

Recovery from Pneumococcal Meningitis

The following report of a case of recovery from pneumococcal meningitis may be of interest.

CASE RECORD

A girl aged 16 suffered a year ago from gonococcal infection. We were asked to see her on the evening of May 16 and on our arrival at 7.30 she was deeply unconscious. Her pupils were widely dilated, there was oedema of both optic disks, she had a temperature of 97° F., a pulse rate of 60 and her respirations were 20 a minute, superficial reflexes were absent, Kernig's sign was negative and her limbs were flaccid. Her mother informed us that on the previous evening she had complained of sore throat and severe frontal and bitemporal headache. She had also had several rigors. On the morning of May 16 the headache was still very bad but the patient did not appear to be very ill. About 6.30 p.m. she brought up a green vomit, and by 7 o'clock she was unconscious.

In view of the clinical findings and of the previous history a gonococcal meningitis was considered not unlikely. Lumbar puncture revealed fluid under so great a pressure that much was lost, but probably between 20 and 30 c.c.m. were removed before the normal rate of flow was established. Prontosil soluble was injected intramuscularly with a quarter of a grain of morphine. The cerebrospinal fluid showed a cell count of approximately 7,000 and the cells were entirely polymorphonuclear leucocytes. Extracellular lanceolate diplococci were present in great numbers, and were provisionally diagnosed as pneumococci.

On the morning of May 17 the patient was conscious but quite blind and she complained of intense headache and frequent vomiting. Prontosil was again administered intramuscularly and by the mouth. On the evening of the same day she was still very restless. Lumbar puncture was again performed and the pressure, whilst still great, was obviously less than on the previous evening and the cerebrospinal fluid was much less turbid. Prontosil was again administered.

On May 18 her condition was improved although she was still restless, blind and incontinent of urine. Prontosil was continued in doses of four tablets a day by the mouth and the pressure was again restored to normal by lumbar puncture.

Dr. Howel Evans of Liverpool reported on the cerebrospinal fluid as follows: "Protein + + +, cells approximately 7,500 per cmm. All polynuclears. Films show a few badly degenerated cocci morphologically resembling pneumococci. Your own stained films are the best, and I agree that the organism appears to be a pneumococcus. The precipitin test is positive against the pneumococcus Type 1 negative against the meningococcus. Cultures remained sterile for twenty-four hours. This may be due to autolysis owing to delay (Bank Holiday week-end). I think the presumptive evidence is in favour of a pneumococcal infection, and I regard the prognosis as very bad."

On May 19 the patient's condition was definitely very much improved. There was no vomiting the pulse and temperature were normal the headache less frequent vision fully returned and she asked for bacon and eggs. Prontosil was still given. Her progress from that time was uneventful and by May 25 she had completely recovered.

The suddenness of the onset and the presence of green pus at the bottom of our centrifuge tubes appeared to point to a rapidly fatal issue. Prontosil was given because the pneumococcus is not far removed biologically from a streptococcus but principally for the sake of doing something. Whether the successful issue was due to this agent or to the repeated cerebrospinal drainage it is impossible to say.

Minsterbury, Westmorland

Reviews

BRITISH ENCYCLOPAEDIA OF MEDICINE

The British Encyclopaedia of Medical Practice including Medicine, Surgery, Obstetrics, Gynaecology and other Subjects Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O. Vol. 3. Cataract to Diaphragm Diseases (Pp 681 illustrated 35s per vol.) London Butterworth and Co 1937

The third volume of this encyclopaedia includes the subject headings from cataract to diaphragm diseases. The list of authors contributing is a representative one and the present volume keeps up the high standard set in the two that have appeared already. The problems of early life, child welfare and health, dentition and child guidance from the psychological point of view, coeliac disease and convulsions in infancy and childhood, receive attention from experts in the subject, while the phenomena and management of the climacteric in women and in men are dealt with by two of the senior editors, Professor James Young and Sir Humphry Rolleston respectively. Among the neurological subjects cerebellar diseases and cerebral plegia are in the capable hands of another editor, Dr F. M. R. Walshe, who is also responsible for the article on affections of the cranial nerves. The sections on sudden and unexpected death, and the relation and responsibilities of the profession to coroners and inquests are informative and valuable, presenting in a useful summary the legal aspects of these matters. The question whether or not to report a death to the coroner often puzzles medical men even of long experience, the indications given by Dr Temple Gray will be of great help in answering this question, and his remarks on the need for clarity in filling up death certificates should be noted, since the registrar may be unable to accept as a cause of death some of a string of diseases unless their sequence, their interrelation, and the actual cause of death is clearly stated.

Of the general medical diseases cholera, chicken pox and cerebro spinal fever are fully dealt with, and Dr J. G. Greenfield has made a valuable addendum to the last in discussing the chemistry and bacteriology of the cerebro-spinal fluid. Sir Arthur Hurst's articles on constipation, colitis and carcinoma of the colon give a clear and succinct picture of the subjects. In the treatment of ulcerative colitis there is considerable discrepancy between the results obtained in general hospitals and in private clinics. Care and nursing affect the result, but antecedent conditions of the patient must bear largely also. There is not yet any consensus of opinion as to specific therapy. A general article on coma, its causes and the methods to be adopted in dealing with cases is noteworthy. The companion article on concussion and compression by Mr L. R. Broster amplifies certain points. Surgeon Commander MacLeod has brought into small space all the essential facts about colour vision, its abnormalities and the means of detecting the colour-blind. The article ends with a summary of present-day theories of colour vision. There are a number of specialist subjects included in this volume, some on eye diseases and some on tropical diseases. The informative articles on cyanosis and infections with coliform bacilli are of more general interest. It is important in the latter to take a wide view of the patient and his complaint, the routine administration of urinary antiseptics without full investigation of the state of the urinary

tract and without excluding any local focus of infection and reinfection cannot be successful. Mr Clifford Morson insists on these points but is rather pessimistic about means of cure.

This volume is, like the preceding ones, well produced and carefully edited. The marginal subheadings give easy guidance for rapid consultation without breaking the continuity of the article to be read as a whole. Printer's errors are rare, in this volume we have noted them only on pages 153, 511, and 585.

NEUROLOGY IN ANCIENT GREECE

Etapes de la Neurologie dans l'Antiquité Grecque (D'Homère à Galien) By A. Souques (Pp 248 45 fr) Paris Masson et Cie 1936

Dr Souques's scholarly work is divided into seven chapters corresponding to the stages through which neurology has passed—namely, the period from Homer to Hippocrates, the Hippocratic period, the age of Aristotle, Herophilus and Erasistratus, Greek medicine in Rome, the age of Galen, and the post Galenic period down to the Middle Ages.

In the Homeric Age nothing was known as to the anatomy of the nervous system apart from the fact that the brain was in the skull and the spinal cord in the vertebral column. The physiology of the brain was also unknown at that time, sensation being located in the organs of the thorax and abdomen, and especially in the heart. As regards Hippocrates, although he had no knowledge of anatomy or physiology, his clinical knowledge was little short of miraculous for the time in which he lived, as is shown by his discovery of paralysis on the opposite side to the lesion in the brain, his account of traumatic and otogenic meningitis, his cure of amaurosis by trephining and his description of apoplexy, generalized and partial epilepsy, ophthalmic migraine, tetanus, cerebral symptoms in alcoholism, hereditary disposition to nervous diseases, periodicity of certain psychoses, Pott's disease, diphtheritic paralysis, sciatica, etc.

In the period between Hippocrates and the Alexandrian anatomists Aristotle was the leading figure. Though an eminent zoologist and the founder of comparative anatomy, his dissections were confined to animals. He had no knowledge of the peripheral nerves, and regarded the brain and spinal cord as different in nature. It was left for Herophilus and Erasistratus of Alexandria by their dissections of human subjects, to give the first description of the anatomy and physiology of the nervous system in man. The cardiac theory of sensation which had been held since the Homeric Age was overthrown, and until the seventeenth century none of their successors made any important contributions to the anatomy of the nervous system.

In the chapter on Greek medicine in Rome Dr Souques states that knowledge of the anatomy and physiology of the nervous system remained stationary, whereas considerable progress was made in the study of nervous and mental disease, in which Aesclepiades, Themison, Archigenes, Rufus of Ephesus and most of all Celsus, Aretaeus and Soranus made important contributions. There is no mention however in any of their writings of tabes, disseminated sclerosis, amyotrophic lateral sclerosis, and many other diseases of the central or peripheral nervous system. Galen is described by Dr Souques as a clinician of value, a valuable anatomist, and an experimenter of genius who does not deserve the oblivion into which his work has fallen. He was guilty.

however, of several great errors, which were chiefly due to the fact that he dissected animals only and did not always carry out their dissection with sufficient care. On the other hand he discovered the recurrent laryngeal nerves and the motor and sensory roots of the nerves, and was the founder of experimental physiology and psychology.

In the period following Galen, which extends down to the Middle Ages, no important discovery in neurology was made and no pre-eminent medical figures stand out. The age was merely one of compilers, of whom the best known were Oribasius and Paulus Aegineta.

DIET AND DIETETICS

Modern Dietary Treatment By Margery Abrahams, M.A. M.Sc., and Elsie M. Widdowson B.Sc., Ph.D. (Pp 328 8s 6d) London: Bailière Tindall and Cox. 1937.

Dietetics Simplified: The Use of Foods in Health and Disease By L. Jean Bogert, Ph.D. With Laboratory Section by Mame T. Porter M.A. (Pp 637 12s 6d net.) London: Macmillan and Co. 1937.

Books on diet follow each other thick as leaves in Vallombrosa. Many are tendentious and incomplete, and few do more than provide work for the printer and relief for the inner tensions of the authors. It is a pleasure therefore to review two books on diet which are sober and up to date and which should be able to look forward to a long life of usefulness. *Modern Dietary Treatment* by Miss M. Abrahams and Dr. Elsie M. Widdowson, is a short handbook on diet as used in medical treatment. It is essentially practical, and of its 300 pages some 200 are given over to diet lists and tables. After a brief description of the constituents of a normal diet and the principles of nutrition the authors proceed to give lists and examples of the great majority of the diets used in medical treatment. Then follow recipes, tables of the chemical composition of foods, biological and metabolic data, and a bibliography. This book can be strongly recommended to medical practitioners and students, nurses and hospital dietitians. There is no other small handbook in the English language with so much accurate information about diets and so little verbiage, and it will be greeted with joy by all those who have struggled to translate menus consisting of crackers, egg plant, and squash into English practice. Infant feeding is rightly omitted. Short as the introduction is, some reference should be made to the important conception of conditioned deficiencies. The section on low salt diets might be expanded to include the dehydrating diets which have been used for tuberculosis, rheumatism, migraine, and vertigo. There is no mention of allergy or elimination diets, and the section on acid and basic ash diets is too brief.

Dietetics Simplified must have been a labour of love, otherwise we cannot see how Dr. L. Jean Bogert, Miss M. T. Porter and the publishers could have produced this detailed well illustrated and well indexed book at so low a price. It is a complete description of the use of foods in health and sickness and is divided into four parts. The first part deals with the principles of metabolism and nutrition; the second part with diet in normal conditions, paying special attention to pregnancy and lactation, infancy and childhood, old age, racial differences in habits of feeding and the construction of family dietaries. The third part gives a complete range of diets for use in disease and the fourth part is composed of laboratory lessons in cooking recipes and tables. The book is therefore a textbook of dietetics but though it is espe-

cially addressed to dietitians it is also considered suitable for the student of home economics and the intelligent housewife. A good deal of information that is scattered through textbooks of physiology, pathology, and medicine is here presented with order and balance, and though some of us may not have quite as much faith as the authors in the effects of satisfactory alimentation, it is a fine and inspiring book. The conception of the doctor as a cross between a Red Indian and Sherlock Holmes, and the associated over-emphasis on clinical diagnosis, die hard in English medical schools. The Germans in their efforts to swallow naturopathy intact have perhaps gone to the other extreme, but it is well to remember that lay people are more interested in prophylaxis and symptomatic treatment than in diagnosis. We hope we shall not be considered neo-Germanic if we suggest that some of the time spent in watching operations or in discussing the differential diagnosis of incurable disease might be better spent in a course of dietetics, and students could hardly begin better than with Bogert and Porter.

PHYSICAL TRAINING

Anatomy and Physiology of Physical Training By Major R. W. Galloway, D.S.O. M.B. Ch.B. R.A.M.C. (Pp 182 42 figures 6s net) London: E. Arnold and Co. 1937.

Experiments in Homework and Physical Education By A. Sutcliffe, M.A., B.Sc., and J. W. Canham M.A. (Pp 194, illustrated 4s 6d.) London: John Murray. 1937.

Health and Muscular Habits By Lieut.-Colonel J. K. McConnell, D.S.O. M.C. and F. W. W. Griffin M.A., M.D. Foreword by Lord Horder, K.C.V.O., M.D., F.R.C.P. (Pp 159, 27 figures 5s) London: J. and A. Churchill. 1937.

In his small book Major Galloway seeks to instruct teachers of physical training in the elements of anatomy and physiology and their application to a scientific system of training. An introduction is contributed by Professor Cathcart. The chapters on muscular action are clear and well illustrated if somewhat anatomical in detail, and the book as a whole succeeds in its object. Short descriptions of the principles of anatomy and physiology must necessarily be inadequate, and open to the criticisms which apply to the handbooks of the Red Cross and St. John Ambulance type. The chapter on corrective exercises, in which the treatment of spinal curvature and the like is described, brings to mind the proverb that a little learning may be dangerous. There is too great a tendency in these days of physical training enthusiasm to assume that the correction of physical defects is the province of the physical trainer rather than that of the doctor. This point might well be more emphasized in future editions. Of the many problems of education there is probably none engaging more attention at the present time than the relative importance of the physical to the mental side and the proper adjustment of the time factor between them.

Readers of *Experiments in Homework and Physical Education* by Messrs. Sutcliffe and Canham will find an interesting account of a series of tests for mental and physical efficiency and their application, designed to throw light on this problem. The results arrived at make no claim to be decisive but indicate good reason for a preference in favour of reading as opposed to writing as homework and for something more than two periods a week in school hours for physical training. The careful and scientific approach to the subject and the restrained restraint of the conclusions arrived at deserve the highest praise.

There could be no better review of the little book *Health and Muscular Habits* by Lieut-Colonel J K McConnell and Dr F W W Griffin than that contained in the short preface by Lord Horder. The book aims at interesting the individual and the value of increasing health by cultivating balance of body and correcting bad habits of posture. It is written in an attractive style with simple diagrams easily understood and is free from the customary set exercises which so often call to mind the gymnasium and drill instructor. Body balance and grace of movement are not only a pleasure to possess and a delight to behold, but also exert a mental stimulus which is not easily overestimated. There are few who could not read this book with advantage, and we commend it most heartily to all.

EXCHANGE OF BODY FLUIDS

Body Water. The Exchange of Fluids in Man. By John P Peters M D (Pp 405 18s.) London: Baillière Tindall and Cox.

This monograph by Professor J P Peters of Yale, deals with some of the most obscure problems in human physiology. The first half is concerned with the exchange of water between the blood, the tissues and the interstitial fluids, the second half chiefly with renal activity. The author has devoted many years to experimental work on the distribution of solutes and water in the human body, and the present volume is an attempt to assemble his ideas in the form of a coherent story. The

result is a masterly review of an extremely difficult subject. The fact that there is no really adequate explanation of the causes of oedema is fairly well known but Professor Peters makes it clear that the manner in which the occurrence of oedema in the normal body is prevented is equally mysterious. Many ideas have been advanced to explain the production of lymph and its final return to the circulation; they all account for a considerable proportion of the facts, but usually finish by evoking some process outside the known laws of physical chemistry and not infrequently one finds explanations couched in the more rigorous terms of physico-chemistry, which contain, buried discreetly in the midst of formulae, some physico-chemical equivalent of the assumption of perpetual motion. The author has successfully avoided such pseudo-explanations for he realizes that until the qualitative nature of a process is roughly understood there is little advantage in attempting to express it in mathematical terms, and he therefore avoids the use of elaborate mathematics.

The uncertainties and apparent contradictions that characterize our present state of knowledge of lymph formation and urine excretion are frankly recognized, and the author makes an attempt to throw light upon difficult problems instead of merely evading them. Recognition of the extreme complexity of his subject naturally makes all the conclusions tentative and incomplete but raises the monograph into the select class of works which are calculated to stimulate further research.

Notes on Books

Dr T WILSON PARR, who is in active practice in North London, is well known as the authority on prehistoric trephining. For many years he has contributed poems—things grave and gay—to the *Cambridge Medical Society Magazine* and to the *St George's Hospital Gazette*. There was some danger of these little works of art becoming fugitive pieces. Fortunately he has been persuaded to collect them, and they now appear under the title of *Immortal Names and other Poems*. They are well worthy of preservation and will give pleasure to every lover of poetry. They show, incidentally, how a medical man can dissipate professional cares by cultivating the Muses. The book is published by the Mitre Press at 5s.

Another instalment of the *Collected Papers* of the Walter and Eliza Hall Institute of Research in Pathology and Medicine, Melbourne, of which Dr C H Kellaway is the director, has now been published in a single volume, covering the years 1935 and 1936. The thirty-five papers are reprints from various medical journals in Australia, Great Britain and the United States.

Weight Reduction Diet and Dishes by Dr E E CLAXTON with recipes by LUCA BURDEKIN is published by Heinemann at 8s 6d. This joint book goes into the subject in full practical detail. It deals with the treatment of obesity by exact caloric diets enforced by a weighing scale for food and abundance of exact diet recipes. No patient who has the energy to follow the detailed instructions will fail to lose weight. The arrangement of the diets and recipes is good and the methods follow well-established lines and principles. The first chapter on famous fat men in history is interesting and amusing.

Although invented over forty years ago it is only recently that the cathode ray tube has become an indispensable piece of electrical apparatus. The advent

of television with the adoption of the cathode ray tube for its reception, has led to improvement in its design and reduction in its cost, so that it is now no longer confined to laboratory use. *The Low Voltage Cathode Ray Tube* (Chapman and Hall, 10s 6d) is written by Mr G PARR, an engineer on the staff of the Edison Swan Electric Company, and it deals thoroughly with construction, operation and applications. To all interested in the cathode ray tube as a means of recording bio-electrical phenomena this book can be recommended because it will give them a sound grounding in the physics and construction of these tubes, which obviously have a big future before them. Only pages 124 to 126 have any direct reference to medicine and here a brief description of the cathode ray oscillographic electrocardiograph is given. Mr Parr's book must therefore be considered as suitable only for those who are taking up the study of the physics of these tubes.

In her pamphlet on *Diphtheria and Constitution* (Leipzig: Georg Thieme, RM 1 60), based on the study of 554 cases of diphtheria which occurred in the Children's Tuberculosis Clinic at Scheidegg from 1926 to 1935, Dr FRIEDA BÖNING comes to the conclusion that children with the lymphatic and exudative constitution are more prone to attacks of diphtheria than others although the severity of the attack is not affected by the character of the constitution.

The greater portion of the *Yearbook of the American Pharmaceutical Association* is occupied by an annual report on the progress of pharmacy. This consists of a series of abstracts from pharmaceutical journals and also from chemical and medical journals. From the point of view of the medical scientist the special value of the report is that it covers many publications which are not included in indexes of medical literature and the provision of short abstracts is of particular value when the journals referred to are difficult of access.

CENTENARY OF LIVERPOOL MEDICAL INSTITUTION

Centenaries interest primarily those who celebrate them, but the historic figures brought to mind by the events of May 30 to June 1 in Liverpool are the heritage of the whole profession. One hundred years ago John Rutter founded the Liverpool Medical Institution 'to give more systematic direction to scientific inquiry, to promote calm,

references to their claims to honour by Emeritus Professor John Hay. In addition to Sir Cuthbert Wallace, Sir Norman Walker, Sir Farquhar Buzzard, and Sir Ewen Maclean, official representatives of the great corporations with which their names are so honourably linked, a very pleasing tribute was paid to the pro-

The Liverpool Medical Institution

temperate, and reiterated discussion amongst those who practise and advance the art of medicine and to remove hindrances to progress in the great cause of public health." On May 31, 1837, the classical building, in which it is still housed was opened. On May 30 1937 celebrations of

this event began in Liverpool Cathedral. The Presidents of the British Medical Association General Medical Council, and the Royal College of Surgeons were there, as well as the Lord Mayor of Liverpool and the Vice-Chancellor of the University. A sermon by the Bishop of Glasgow summed up in a word the changes in medicine and theology that the century has seen, and presented the need for a stand for freedom of thought in both religion and science in the face of the claims of the totalitarian state. The Guild of St Luke St Cosmas and St. Damien met for Benediction on the site of the new Roman Catholic Cathedral.

On Monday, the 31st, a hundred years to a day from the first meeting of the Liverpool Medical Institution there was a crowded gathering to witness the conferring of honorary membership upon distinguished guests. The latter were presented with happily appropriate

references in Manchester in the person of the President of the Manchester Medical Society Professor Fletcher Shaw. Perhaps, however, there was the greatest enthusiasm for similar honours paid to members of the Institution itself, Sir James Barr, a member since 1874, Mr

Frank T. Paul, since 1875, and Mr Thurstan Holland, since 1888. Ill health unfortunately prevented the presence of the first mentioned two. Professor Hay referred to the great services these men had rendered to the profession, both in scientific contributions to our knowledge and in the medico-political field. To many present at the ceremony a reminder of their personal gifts of charm and character was unnecessary. Dr Hugh Clarke received—again in absentia unfortunately—the congratulations of the Institution on completing fifty years of membership and

Hugh Owen Thomas and Robert Jones Memorial
Library of Orthopaedic Surgery

warm tributes were paid to his personal qualities and notable public services by Dr W. B. Bennett and Dr A. E. Hodgson.

Medical Journalism a Hundred Years Ago

Then followed a stimulating address by the President for the centenary year, Professor R. E. Kelly, on the sub-

ject of "Surgery 100 Years Ago" Professor Kelly sketched the social atmosphere in which the surgeon of those days lived, the interests of intelligent men of his time, and the course of his career before he reached the staff of the infirmary or dispensary. He alluded at some little length to the two great surgeons of the end of the eighteenth century, Henry Park and Edward Alanson, who were famous as pioneers in the excision of joints and in the perfection of amputation technique respectively. Alanson was also to be remembered for his advocacy of country hospitals, iron bedsteads, clean linen and open windows. To these two men, with a third surgeon called Lyon, came the idea of forming a reading club about 1770, and from this seed through many vicissitudes there came to full fruition ultimately the Liverpool Medical Institution. Most entertaining were Professor Kelly's references to the medical literature of 100 years ago. His extracts from the *Lancet* gave a telling picture of the hard hitting methods of medical controversy in those days and incidentally threw a strong light on the fearless policy of the Editor in exposing practices that brought discredit on the profession no matter what the standing of those whom it might be necessary to attack.

The warm appreciation of his audience was expressed by Dr Stallybrass and Mr G C E Simpson, ex-presidents of the Institution. Before the end of the meeting the honorary treasurer, Dr Arthur Gemmell, made an appeal for subscriptions to a Centenary Fund to provide for heavy capital expenditure which town planning might soon make necessary. A sum of £5000 was aimed at donations towards which would be very welcome from all friends of the Institution.

In the evening there was a banquet at the Adelphi Hotel attended by many distinguished guests representative of all forms of public service on Merseyside, as well as by some 200 members. More than one of the excellent speeches which followed the banquet emphasized the need for closer and more active co-operation between voluntary and municipal medical services in securing adequate and efficient treatment of the sick.

Library of Orthopaedic Literature

Tuesday, June 1, saw the conclusion of the celebrations. In the afternoon Mr Rowley Bristow, President of the British Orthopaedic Association was invited to declare open a room in the Institution which has been entirely replanned as a library of orthopaedic literature. "In memory of Hugh Owen Thomas and Robert Jones the Founders of Orthopaedic Surgery. The impetus for this was provided by a collection of books on orthopaedics which was received in response to the Sir Robert Jones' Memorial Appeal. The new library is intended to gather from all corners of the world new works on the subject as they appear. By making such works available to succeeding generations interested in this speciality it is hoped to provide a permanent memorial to these two great sons of Liverpool in real harmony with their genius. Interesting reminiscences were given by Mr T R W Armour and Mr Thurstan Holland of the days when orthopaedic surgery as we now know it was first being tried out in Owen Thomas's house, No 11, Nelson Street and Mr Thurstan Holland revealed how it was only by the generosity and constant encouragement of Sir Robert Jones that he ever began the practice of radiology.

Later in the afternoon Mr Rowley Bristow delivered the triennial Hugh Owen Thomas Memorial Lecture on "Fractures—Some Principles Restated." These principles he said might be briefly stated to be first reduction second fixation pending union and third protection during consolidation. Almost of equal importance however was attention to the injuries of soft parts which always accompanied a fracture by exercise designed to prevent muscular atrophy during the period of fixation. Lack of care in this direction led to the decubal ulcers which the fracture was sometimes due to the bony injury. In the treatment given. Examples were quoted of

fractures where this care of the soft tissues was all-important, and x-ray slides illustrated special types of difficulty in reduction, as well as the prevention and treatment of secondary displacements. Mr Bristow declared himself a whole-hearted believer in closed manipulative reduction in all but a few cases. He expressed a preference for the use of skeletal traction in all difficult cases in the lower limbs. In fractures of the neck of the femur he favoured pinning by the Sven Johansson technique. He was accorded a hearty vote of thanks.

In the evening a most enjoyable reception was given by the Lord Mayor at the Town Hall to members and their guests, a very practical expression of the sympathy and interest he had shown throughout the proceedings.

THE ARRIVAL OF THE BASQUE CHILDREN AT THE PORT OF SOUTHAMPTON

BY

H. C. MAURICE WILLIAMS, M.R.C.S.,
L.R.C.P., D.P.H.

*Medical Officer of Health and Port Medical Officer to the
County Borough of Southampton*

The arrival of the Spanish liner s.s. *Habana* on Saturday May 22, at Southampton, with 4056 refugee children on board from Bilbao was an event of national interest and historical importance as the first occasion that a shipload of refugees has arrived in Great Britain. During the great war the Belgians who sought refuge in this country came in small parties. It is therefore of public health interest to record the procedure adopted by the Southampton Port Medical Service in dealing with this vessel and the disembarkation of the children to the camp that had been prepared for their reception at North Stoneham, on the outskirts of Southampton.

The first official notification of the vessel's departure from Bilbao was received during the morning of Friday, May 21, when the expected time of arrival was given as late on Saturday. Conferences had therefore to be arranged on the Friday and on Saturday morning with the immigration and customs authorities, the National Committee for Spanish Relief, the Southern Railway, and the shipping agents to discuss various details connected with the vessel's arrival.

On Saturday morning a wireless message from the vessel was received giving the state of health on board and this message indicated that the children were suffering from severe sea sickness. In accordance with Section 6 of the Port Sanitary Regulations 1933, the master of a foreign-going ship is obliged to notify by wireless, either direct or through his agents to the port sanitary authority of an approved port the presence of any condition requiring their attention, and this message must be received not more than twelve and not less than four hours before the ship arrives in the port sanitary district. Instructions were given to the pilot to anchor off Fawley in Southampton Water, and there await the arrival of the port medical officer.

At 5 p.m. on the Saturday the *Habana* escorted by a British destroyer, was signalled off the Needles and on receipt of this information the port sanitary staff, accompanied by customs and immigration officials left the docks in the port sanitary launch to board her as arranged. Another launch followed with supplies of milk, glucose, meat extracts and medical requisites.

Conditions on Board s.s. "Habana"

It was an extraordinary spectacle to see a vessel normally capable of carrying between 400 and 500 passengers steaming up Southampton Water with every inch of her deck covered with human beings. Even more extraordinary were the conditions found on board.

Children all herded together in the public rooms, in the alleyways, and on all the decks. Some were lying rolled in blankets, others running about the ship screaming, and a few, cool and complacent, appeared to accept the circumstances of their arrival in a strange land, having been parted from their parents, without any emotion. It was with some difficulty that we were able to reach the ship's hospital to see a boy of 12 who, later the same evening, was removed by launch and ambulance to the borough hospital for an operation on a strangulated testicle.

After consultation with the two English doctors who had made the selection and carried out a detailed examination of the children before embarkation and who had travelled in the ship from Bilbao, we were satisfied that no infection of a major character existed on board, and therefore modified practice was granted to the ship, permitting her to proceed to an inner mooring station next morning for a detailed medical inspection.

Suitable accommodation had to be found for the purpose of carrying this out, and this was no easy matter with so many persons on board. It was, however, decided to use the two main saloons, which were roped off to provide two entrances, and one exit on to the main gangway. Details as to the situation of the medical officers' examining cubicles and the provision of screens and other equipment were matters that had also to be considered on this occasion.

After lying off Fawley for the night the *Habana* steamed up Southampton Water to Berth 106 in the New Docks at 8 a.m. on the Sunday. Hundreds of the public, with Press representatives and photographers, had collected along the quay, but no person without an official pass issued by the port sanitary department was permitted to approach Berth 106 or go on board. The names and addresses of all who were given these official passes were recorded, in order that the health authorities throughout the country might keep them under a surveillance in the event of any major infection being discovered among the persons on the ship.

Medical Inspection

The gangway was fixed and the medical, nursing, and sanitary personnel of the department proceeded on board. Accompanying the children there was one female adult to approximately every twenty children. It was therefore thought expedient to arrange for these adults to be examined before we commenced on the inspection of the children, in order that they might be instructed to marshal the children in groups of twenty, so far as possible according to age and sex.

The saloons were then cleared of all except those taking part in the medical and immigration inspection, and within half an hour the children were lined up in queues and the inspection commenced. Nine medical officers of the department each in a separate screened cubicle took up their positions in the line of the queue. A health visitor assisted each doctor by stripping the children to the waist. In examining each child special attention was paid to the eyes for trachoma, the head for ringworm, lice or nits, and the skin for rashes and lice. The heart and lungs were also tested in detail to decide on those fit to live under canvas.

On completion of the examination each child was dressed by a health visitor and passed on in the queue to a sanitary inspector who stamped the identification card attached to each child, indicating that he or she had been medically examined. In addition he also tied a coloured tape on the child's left wrist, which served as a code as to destination. White tape indicated clean, and allowed the child to proceed direct to camp; red tape indicated "verminous," and the wearer was sent to the Corporation baths for de-lousing; blue was for "infectious or contagious" conditions and for entry to the isolation hospital or other institution. Blue and white tapes were

used for any other condition requiring general hospital treatment.

After the medical inspection was completed each child was passed on to the immigration officer, who stamped the disk officially; the children then proceeded down the main gangway, at the foot of which sanitary inspectors and health visitors collected them into groups according to the colour of the tapes and arranged for their immediate disposal in the following ways: clean children went direct by motor omnibuses to the camp, verminous children were taken in lorries to the Corporation baths for de-lousing, and the hospital cases were transported by the Corporation ambulances to the appropriate institutions.

General Physique of Children

The medical officers were surprised to find that a large majority of children showed no marked sign of malnutrition, although most of them had for months lived in Bilbao on fish and black bread and had spent the days and many nights herded together in bomb proof shelters. The Public Medical Service in this particular province of Spain, according to the information obtained from the two English medical officers, is of a very high standard. Many of the children were thin, but the general impression gained, especially before they stripped, was that they were, generally speaking, an alert, intelligent group of children, who compared favourably in physique with our own children. The clothing as a rule was very good, and when that of the verminous ones was taken away from them for disinfection many of them wept. At the Corporation baths we were allowed to use forty of the slipper baths, and with the assistance of many voluntary and willing helpers, together with twelve barbers, 712 of the children were de-loused and fitted with complete sets of clothing, the latter being supplied by the Spanish Relief Committee.

At 7 p.m. on the Sunday medical inspection ceased for the day, the medical staff having worked continuously for ten hours and having dealt with 3,278 children. On the following morning the remainder were examined, the task being completed by 11 a.m.

My department received very great assistance from many voluntary workers and from the National Committee for Spanish Relief in providing transport, etc. It was only by the co-operation and hard work of all concerned that we were able to accomplish what, I believe, is a record in the annals of the Port Medical Service—the detailed examination of 4,056 children in twelve hours. Public opinion appears to be somewhat divided about the acceptance of these children, but I think the only answer is, 'What would we think if our own children were subjected to similar privation and danger?'

The Save the Children Fund which as originator of the Declaration of Geneva (Child Welfare Charter of the League of Nations) has a special concern for the welfare of children and young people, passed a resolution at its Council meeting on April 22 welcoming the Factories Bill 1937, in so far as it represents an advance on existing conditions affecting children and young persons. The Council desires however, to place on record the conviction that the Bill will fail to reflect the humane and enlightened public opinion of the day unless it is so amended as to ensure that no child shall be employed in a factory before the age of 15, that no child or young person shall in any circumstances be permitted to work more than forty hours a week, that no overtime be permitted in the case of any young person under 18 years of age, that holidays with pay be assured to all children and young persons, that the hour of leaving work may be sufficiently early to enable children and young persons to take advantage of available opportunities for education and recreation, and that the clause providing that the Home Secretary may suspend Part II of the Bill (dealing with safety) until 1940 be eliminated."

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 12 1937

THE INSURANCE CAPITATION FEE

The Court of Inquiry into the amount of the capitation fee to be paid to insurance practitioners appointed by the Minister of Health and the Secretary of State for Scotland has now made its report. From January 1 next the pool out of which insurance practitioners are remunerated will be calculated at 9s per insured person as at present. This rate, however, is to apply alike to all insured persons, whatever their age of entry into insurance, and is apart from the special arrangements as to the supply of drugs and appliances and from any payments to meet the special conditions of practice in rural or semi-rural areas. This result will be received with some disappointment by the medical profession in general, although they will appreciate the vindication of the contention that the new class of juvenile entrants to insurance should be at the uniform and undiminished rate.

The personnel of the Court and the full and exact terms of reference thereto were given in the *Supplement* to our issue of May 8 last (p. 272) the memorandum and correspondence in which the case of the Insurance Acts Committee and that of the Ministers were placed before the Court were set out in the *Supplement* of May 29 (p. 313) and the proceedings before the tribunal during the four days of its sitting were reported in that of June 5 (p. 341). The decision of the Court will of course be loyally accepted by all the parties to the inquiry, and a perusal of our columns as just indicated will enable readers both to appreciate the restricted nature of this inquiry as compared with the wider reference to a former Court some thirteen years ago, and to judge the cogency and relevance of the arguments and facts brought to the notice of the Court by either side. These are all of much importance to the public and to the profession as a whole, as well as to insurance practitioners.

At the Court of Inquiry in 1924 the appropriate amount of the capitation fee was being inquired into *de novo* and the Court was necessarily occupied with such general questions as the nature and quality of the services rendered, the number and variety of the items of service which this necessarily entailed, the remuneration as compared with that of other forms of contract practice and with

that accepted in other branches of the medical profession, the proportion of expenses in relation to the gross receipts of practice, and the cost of living in professional households compared with that of other classes of society. The present inquiry, though not less important, was simpler in so far as it was confined to the consideration of any changes which may have since taken place in some of these factors, together with any adjustments which should be made by reason of the proposed legislation to admit to insurance employed persons under the age of sixteen years. On the previous occasion some of the factors particularly the proportionate amount of professional expenses, had, in the absence of sufficient information, been accepted as an agreed guess, whereas it has since been found possible to ascertain them more accurately while other factors, especially the number of items of service per insured person had been calculated as the result of inquiries by methods admittedly imperfect, but which have been greatly improved and extended. It is clear, therefore that some of the standards accepted as entering into the award of 1924 themselves required some modification before they could be surely taken for the purpose of comparison with present-day conditions, and it is really this which seems to have led to the more pronounced differences between the statistical contentions of the two parties in the recent inquiry.

Whatever may have been the weight attached to these statistical differences for the purpose of balancing the award, it is the wider and more general considerations as to the quality and nature of the service which are of more concern to the public and to the profession at large. There is now, happily, in spite of minor criticisms, complete agreement as to the generous interpretation which many insurance practitioners give to the limiting words that define the scope of their contract and as to the high standard of work within that scope which is maintained by the great majority of them, so that the then Chief Medical Officer to the Minister of Health lately described the insurance service as "one of the most effective branches of the public health service", and this high standard has been stated, on the same authority to be "yearly rising". The Insurance Acts Committee was wise in emphasizing this, and in placing in the forefront of its case that in regard to national health value, to medical responsibility and to the time factor in respect of individual attention alike the worth of the service had been materially enhanced during even the last dozen years. It is impossible to approach any mathematical assessment of the first two of these matters and with regard to the third there can be no exact calculations.

significant, however, that in the one instance of a large practice about which evidence was given before the Court, whereas the clientele had increased by 70 per cent the number of consultation hours devoted to them had had to be multiplied fourfold. Every practising doctor knows that these things are true, and the amazing paragraphs under the heading "Nature of Services Rendered" in the memorandum of the Ministers (*Supplement*, May 29, p. 320) demonstrate nothing except the remoteness of the Health Ministry and Department, and even of some of their medical officers, from the realities of present everyday medical practice.

It is necessary to speak plainly on this point, for it is profoundly disquieting, and it seems to have been imperfectly appreciated by the Court. Does it represent the real attitude of our health officialdom to the body of practical workers in the health field? While officialdom is willing to admit a high standard of work within a certain scope, has it no more understanding than this of what that scope actually is? There is evidently a misconception of the relationship of hospital practice to private (including insurance) domestic practice and of the degree of responsibility which the general practitioner constantly undertakes, and an imperfect realization of the volume of preventive work he is constantly doing in the ordinary course of his daily activities. It is grotesque to suppose that there is only a definite amount of medical work to be done and that if there is an increase in that carried out at hospitals there is so much the less for the general practitioner to do. On the contrary, though the adjustments between the two kinds of work are not yet all that they should be, it is true to say broadly that an increase of work in the one field carries with it the almost necessary implication that the work in the other fields must have increased also. Further, there are not a small number of cases in which the responsibility of deciding that hospital or operative work must be undertaken may be even greater than that involved in the carrying out of that work itself, and health guidance may be as important and anxious as manipulative treatment though it exercises an altogether different kind of skill.

Even more disquieting than the paragraphs in the memorandum referred to was the evidence given by two of the deputy regional medical officers of the Ministry of Health. These officers hold positions of importance and influence, and are supposed by reason of their standing and of their own experience of practice in a not too remote past to be available to help and advise less experienced practitioners in several aspects of their insurance service. Yet as soon as the evidence of

one of these officers had been given Dr. Dain was obliged to draw attention to "such an extraordinary account of conditions in general practice," and to ask leave to call an additional witness typical of the general high average of practitioner, who gave an account of those conditions which was completely different but which will at once be recognized by his fellow practitioners as a picture and not as a caricature.

It remains to express appreciation of the general fairness and moderation with which Mr. Harrison presented the case for the Ministers, and to acknowledge the skill which was manifested both in the memorandums and in the actual conduct of the proceedings before the Court on behalf of the Insurance Acts Committee.

HEPATONEPHRITIS

Though the conception of hepatonephritis had been put forward by various French authors, it was not till the discovery of the icterohaemorrhagic spirochaete of epidemic jaundice by Inada and Ido that much attention was paid to it elsewhere. During the war of 1914-18 crowded conditions brought epidemics intensively before the profession, and epidemic jaundice, or Weil's disease, was described among the combatants of both sides. Stokes and Ryle particularly contributed to the better understanding of the symptoms and course of the disease on the British front in Flanders. In this complaint the features are an acute febrile illness with jaundice and renal involvement, and in severe cases much toxæmia. The progress of knowledge and research has led to development on two lines. The carrier of the infecting spirochaete is the rat, and the infection was spread to epidemic proportions in the rat-infested trenches and dug-outs of the war. The spirochaete is excreted in the urine, so that workers in contaminated mud and sewer slime may become infected through abrasions of the skin of legs and hands. Minor epidemics have occurred in sewer workers and in miners. There has thus been a tendency to refer all hepato-renal manifestations to a spirochaetosis, where spirochaetes can not be demonstrated in blood, urine, or tissues; some authors go so far as to suggest a cryptogenic spirochaetial infection.

The reaction against this one-sided pathology has been increased by the discovery that many toxic substances—phenylquinoline, tetrachlorethane, lead (acute poisoning), apioi, and salts of uranium—cause the typical syndrome of hepatonephritis similar to those cases of poisoning after phosphorus chloro-

form, or mushrooms observed from time to time. Among infections with *B. perfringens* and in rare cases of pneumococci, staphylococci, and *B. paratyphosus* a form of hepatonephritis may occur, while yellow fever affords an example where the aetiological factor is a virus. There is thus a fairly widespread group of diseases which fall under the heading of hepatonephritis, but not every affection simultaneously of liver and kidneys should be included. Maurice Derot and Renée Derot-Picquet, who have worked a great deal on the subject and have brought together their clinical observations in a useful brochure,¹ would define hepatonephritis as a disease characterized by simultaneous evolution of manifestations in the liver and kidneys, the alterations in these organs being determined by one and the same cause, whether infectious or toxic. Among the infectious causes undoubtedly the most important is the *Spirochaeta icterohaemorrhagiae*, but others occur in the virus of yellow fever, the treponema of syphilis, various tropical diseases, malaria, dengue, and recurrent fever, and, among the bacteria, various anaerobes as well as the cocci and typho-paratyphoid group. The toxic causes are the heavy metals arsenic, lead, and gold, phosphorus, chloroform, carbon tetrachloride, mercurochrome, and especially apiol, which has been responsible for many grave haemorrhagic cases with symptoms of polyneuritis or tetany. In a certain number of cases no assignable aetiological factor has been found. In severe cases the liver becomes enlarged and swollen, then degenerates and necroses to a state of yellow atrophy; the kidneys are congested, with glomerulitis and diffuse interstitial infiltration. Not all cases come to necropsy, however; many are curable, leaving varying amounts of liver and renal damage as sequelae.

The symptoms are jaundice and alteration in size of the liver with albuminuria and diminished urinary excretion. These signs are often accompanied by haemorrhages and ecchymoses and by severe disturbance of the nervous system from meningeal involvement. In most cases there is fever and loss of weight though the muscle-wasting may be obscured by oedema in many patients. Even in severe cases recovery may take place with more or less impairment of function of liver and kidneys subsequently. Treatment is difficult, and consists in supporting the patient's strength, except in the rare cases where there is a specific antidote for the cause, such as an anti-spirochaetal serum or a serum protective against the gas-oedema bacilli.

THE CHEMISTRY OF ATHLETIC RECORDS

The attempt to isolate the feature or features which explain athletic efficiency is of interest alike to physiologists and to students of athletics. To a considerable degree such attempts are disappointing since superiority depends upon co-ordination of the many factors comprising a complex machinery or upon a still more elusive biochemical factor. American physiologists are fortunate in their access to a large amount of first-class athletic material for experimental purposes and in their opportunities for investigation. Some recent results¹ from the Rockefeller Institute for Medical Research, New York, applying to five middle-distance runners of international renown, will appeal to all athletically minded in this country, for of the five Lash, Cunningham, San Román, and Venzke appeared at the White City Stadium on August 15 of last year when the British Empire met the United States in a post-Olympic contest. In general it is agreed that the occurrence of fatigue after muscular exertion is bound up with the accumulation of lactic acid and it may be a matter for speculation whether the trained athlete differs from the untrained through reducing this accumulation by better motor efficiency, or by his superior circulation ensuring a better oxygen supply to his muscles or by his ability to tolerate a higher lactic-acid concentration, or possibly on account of all of these. During the most severe exertion of which a man is capable lactic acid is produced at the rate of 3 to 4 grammes per second and as the maximum concentration that can be tolerated is of the order of 90 grammes the duration of a maximal effort would be limited to 30 seconds since in that time oxidation of at least 15 grammes would be possible. It is of considerable interest to reflect that this estimate of the limit of extreme effort based upon chemical investigation is supported by the practical experience of athletes that thirty seconds represents the limit of supreme exertion granted sufficient determination and fortitude to "go all out." As might have been expected the oxygen intake of the trained and untrained man was found to be the same when comparatively low grades of exertion—for example a walk at the rate of 5.6 kilometres an hour—were undertaken. At higher grades the oxygen intake of the trained man was much greater, the lactic acid was kept at a lower level. The efficiency for example of Lash when running at the rate of 18.7 kilometres an hour for five minutes enabled him to consume 4.96, 5.08, and 5.1 litres of oxygen successively in the last three minutes of the run and to finish with a blood lactic-acid concentration of only 47.5 mg. per cent. In a final experiment Lash ran (for a distance not stated) at the rate of 21.6 kilometres per hour, which is approximately his speed when he created a world's record for two miles. In this experiment he reached an oxygen intake of 5.35 litres a minute. Related to basal metabolism this means that he elevated his metabolic rate to 21.4 times its basal level as compared with 14.5 the maximum of the best untrained man. This far exceeds all previous estimations of a similar character. It is of course unwise to apply uncompromisingly the cold-

¹ *Science* 1937, 85, 409.

blooded results of the laboratory to those produced under the stimulus of emotion—intense excitement, the influence of competition, the desire to win, and so on. In some cases the unsuspected sources of human endurance may be well beyond those which the laboratory would indicate. Alternatively, some temperaments may lead to better performances in the laboratory. Lash, one recalls was a failure at the White City contest. Although subsidized research in this subject on the elaborate lines of our transatlantic colleagues is not practicable in this country, the importance of British activities must not be belittled. The pioneer contribution on lactic-acid metabolism, the seed of all research is credited to Fletcher and Hopkins. The classical work of Starling on the heart and of Haldane, Barcroft, and Douglas upon respiration is accepted as of supreme authority. Bainbridge's *Physiology of Muscular Exercise* published in 1918, has been an inspiration to all subsequent workers. A. V. Hill, uniting physiological and mathematical experience to athletic interest and ability, in his fascinating experiments upon human machinery originated the present trend of investigation, and Adolphe Abrahams has applied himself to what might be termed the clinical side of the subject. The liberality with which the British workers are quoted is testimony to the value attaching to their results.

THE LIVERPOOL MEDICAL INSTITUTION

The Liverpool Medical Institution was formally opened on May 31, 1837, and on another page we give an account of the celebrations which have marked the centenary of its foundation. From time to time the institution has moved its local habitation but it has always gone from strength to strength, availing itself of the local *esprit de corps* which is so pronounced a characteristic of the North Country. The present issue of the *Liverpool Medico-Chirurgical Journal* (vol. 45, No. 1, 1937) is remarkable, and reflects the greatest credit on Dr. J. Murray Bligh, the editor who introduces it with a short preface. There are two inaugural addresses: the one by Professor R. E. Kelly, president of the institution during the present centennial year, the other by Mr. G. C. E. Simpson who was president in 1936. Professor Kelly treats of "Surgery One Hundred Years Ago" and reprints the address given by Dr. John Rutter on May 31, 1837. Mr. Simpson writes about "The Liverpool of our Founders" and gives an appalling account of the social and sanitary condition of the town as it was until comparatively recently. Both addresses are of great general interest even to the ordinary reader and still more so to the many distinguished alumni of the University of Liverpool. Both too are lavishly illustrated. Next to the addresses comes an article by Mr. C. Thurstan Holland entitled "On X-Rays in 1896" and finally a very valuable Note on Early Liverpool Doctors and Ship Surgeons by Dr. Bosdin Leech. He gives a list of names of medical men whose wills were proved in the Probate Court of Chester from 1692 to March 1, 1820—a most laborious task but with commensurate results for those who are doing the spade work of medical history.

NERVOUS LESIONS IN EXPERIMENTAL VITAMIN B DEFICIENCY

Since the discovery that vitamin B consists of at least two components—the one heat-labile, the "anti-neuritic" factor, B₁, the other thermostable, the so-called "pellagra-preventing" factor, B₂ (known in America as vitamin G)—much experimental work has been done to study the lesions produced in animals by the absence from the diet of both or one or the other, of these two components. At a meeting of the American Neurological Association Zimmerman, Cowgill and Fox¹ gave the results of their experiments in which they attempted to produce a chronic neurological disease in dogs by feeding them with a minimal quantity of vitamin B₁, the diet being adequate in all other respects. The animals were divided into groups according to the amount of vitamin B₁ they received, this being supplied in varying doses in the different groups in the form of a powdered liver extract. Those animals whose diet contained some but an inadequate amount of this vitamin developed muscular weakness and ataxia. Before the experiment each dog had been trained to do such simple tricks as standing on its hind legs and maintaining its balance on a turn table. Subsequent inability to perform these tricks whilst on the vitamin free diet was used as a clinical test of incoordination. Twelve animals out of fifteen on this diet grew progressively weaker, gave evidence of incoordination, and developed vomiting and diarrhoea. Death occurred at periods varying from 102 to 599 days. In twelve control animals on the same basic diet plus an adequate supply of vitamin B₂ no disease arose. Pathologically, the affected animals showed the changes of a peripheral neuritis with involvement of the posterior nerve roots and degeneration of the posterior columns of the spinal cord. No changes were found in the nerve cells of the brain or cord. In the discussion which followed the reading of the paper a suggestion was made that caution should be exercised in accepting the lesions in the spinal cord as the direct result of lack of a specific vitamin and the work of Edinger was quoted in support of the suggestion. He assumed that in any debilitating condition neural paths which are made to function excessively may become exhausted and finally, degeneration may occur in them. In these experimental dogs the movements which they had been trained to perform and by which they were constantly tested involved the continued functioning of the nerve fibres in the posterior columns conveying the sense of position. It was not surprising therefore that these fibres should be the first to degenerate whatever the cause of the disease. This observation is supported by the experimental work of Davison and Stone² who investigated the lesions produced in rats by deprivation of both B₁ and B₂ factors and also the effect of total starvation and starvation in spite of adequate vitamin B rations. In animals totally starved and in those starved but supplied with enough vitamin B they found even more intense changes in the nervous system than in the rats deprived of vitamin B₁ or of both B₁ and B₂. The lesions of a peripheral neuritis occurred in all the

² Arch. Pathol., 1937, 23, 207.

animals and occasionally at the periphery of the spinal cord there was degeneration of the myelin sheaths. Severe cell changes consisting of vacuolation and necrosis, with small areas of haemorrhage were also observed in the spinal cord and the mesencephalon. The fact that all these pathological lesions can appear in animals simply deprived of food is strong evidence that, however well dietetic experiments may be controlled, conclusions based upon them must be accepted with reserve.

SELECTIVE COLLAPSE

The treatment of pulmonary tuberculosis by artificial pneumothorax aims at putting the affected part of the lung at rest. If this can be attained without collapse of the healthy parts it will be all to the good of the patient. Since Parry Morgan first drew attention to selective collapse in 1912 radiology has brought this phenomenon more and more to the notice of clinicians when only one lobe or part of a lobe is diseased and there are no interfering pleural adhesions that lobe collapses at a pleural pressure which alters but little the size of the other lobe or lobes. The theories of the mechanism underlying selective collapse are fully discussed in two papers recently published by F. Cardis¹ and by H. Warembourg and R. Swynghedauw.² The tendency of tuberculous tissue to heal by fibrosis gives the increased retractility that would account for more rapid collapse of the diseased area, but not for the fact that the whole lobe collapses including the healthy portions. Parodi believes that the weight of the lung is an important factor: the introduction of air into the pleural cavity eliminates this factor and the greatest benefit is obtained by the part of the lung most affected by the weight of that organ—the diseased portion. Cardis points out, however, that this argument could have force only in regard to the upper lobe: yet selective collapse is seen in the others as well. Warembourg and Swynghedauw also reject Parodi's theory but believe that the weight of the lobes helps to determine the relative position of the lobes in the treated lung. Cardis concludes that only one mechanism will account for collapse of the whole of the affected lobe—immobilization by reflex nervous action, a phenomenon comparable with muscular contraction round a diseased joint or in the abdominal wall in peritonitis. The other two authors carried out experiments in healthy dogs. Each lobe of the lung was removed and its elasticity studied by a method they describe. The upper lobes were found to be slightly more elastic than the lower: they believe these findings apply to man. They also obtained support for the theory of a nervous factor in experiments on patients with an artificial pneumothorax. The pleural pressures were read before and after an injection of atropine. In two thirds of the patients the pressure was increased by one to four centimetres of water in both inspiration and expiration. Atropine did not alter the pleural pressure where the collapse was strictly selective and the other lobes were still expanding. On the other hand it had a definite effect in "contraselective" cases

when in spite of a negative pleural pressure the healthy lobes were well collapsed, and in those in which the whole lung was collapsed with a definitely negative pleural pressure. Atropine thus in some way allows the "expansion" of the healthy parenchyma. The authors tentatively suggest its use in those patients in whom the healthy lobes of the treated lung are unnecessarily collapsed.

MATERNAL MORTALITY

In recent years a number of investigations into the causes of maternal mortality have been conducted both in this country and in the USA and have resulted in remarkably similar conclusions. In 1933 the Obstetrical Society of Boston appointed a committee of nine physicians to make a study of the maternal deaths in Boston for the years 1933–5 inclusive and this report has just been published.¹ During this period there were 47,892 live births and 1,336 stillbirths—in all, 49,228 deliveries resulting in 318 deaths, a mortality rate of 6.4 per 1,000. Deaths due to abortion, ectopic gestation and diseases associated with pregnancy are included in this review and the committee having studied the death certificates filed at the State House added forty to the official number of deaths issued by the Department of Health. Perhaps the most surprising feature of the report is the statement that phlegmasia alba dolens, embolus and sudden death accounted for forty-four deaths, some operation having been performed in thirty of the cases. Anaesthesia was responsible for thirteen deaths and the toxæmias of pregnancy for a further fifty-one. Seventy-four deaths were attributed to puerperal septicæmia which in fifty-three cases supervened after operative procedures. More than one-quarter of the fatalities, seventy-eight, to be precise, followed Caesarean section, thirty-one being ascribed to sepsis. There was a further death due to rupture of the uterine scar of a previous Caesarean section. If it be assumed that the mortality rate associated with Caesarean section was 10 per cent. then it follows that 1.6 per cent. of all pregnant women in Boston were subjected to this operation. It is significant that Montgomery² found that the death rate over a ten-year period from Caesarean section in a charity service at Philadelphia was 6.1 per cent. and that the high mortality was by no means the only objection to the operation. He concluded that it is "an unsatisfactory recourse in the impossible obstetric situation." Paradoxical as it may sound it would nevertheless appear to be true that the excellent results from this operation which are obtained by a few select surgeons have encouraged its abuse by those unqualified to perform it, and have led to the partial substitution of obstetric surgery for normal midwifery. The committee did not hesitate to report that in its view many of the deaths were due to bad obstetrics. It found that of the fifty-one women who died from the pregnancy toxæmias only seven received adequate ante-natal care. Of the seventy-four deaths from sepsis twenty followed normal confinements and the committee states that "lack of proper technique must

¹ *Arch. méd.-chir. Appar. resp.* 1936 11 341

² *Ibid.*, 1936 11 354

² *Amer. Journ. Obstet. Gynec.* 1936 31 968

be assumed that twenty operative delivery cases should have died allows of but one conclusion—the operators' technic was poor." Referring to cases of Caesarean section performed for disproportion, the committee remarks that "when it is known that a certain number of these cases were done by men who have had absolutely no training in obstetrics the indication is open to question." The Boston report is fearless and gives the results of midwifery in a city well supplied with efficient maternity services, results which are presumably better than obtain in the country as a whole. Although it is a pity that a statistician was not co-opted to the committee, it is to be hoped that this report will obtain the publicity it deserves. Every inquiry into the causes of maternal mortality has shown that much of it is preventable.

THE HEART IN EMPHYSEMA

The opinion, based on pathological studies, that the right heart enlarges in chronic lung disease with emphysema has only tardily been shared by those who study the living subject. The reasons for this are, first, the difficulties of recognizing cardiac failure in the presence of emphysema, and, secondly, the particular type of cardiac change which may result, which does not appear radiographically as a general or transverse enlargement of the heart. Moreover, the issue has been confused by the fact that primary cardiovascular disease, with its own particular effects on the heart and great vessels, is frequent in the subjects of emphysema. A study of the radiological appearances in eighty patients by J. Parkinson and C. Hoyle¹ shows that definite changes in the heart and in the pulmonary vessels appear in a large proportion of cases. In the anterior view the heart may look small the transverse diameter being either normal or less than this by reason of the low position of the diaphragm, which tends to elongate and at the same time to narrow the cardiac shadow. The conus of the right ventricle and the pulmonary artery may, however, be more prominent than usual, the former giving evidence of the early stage of enlargement of the right ventricle. In the antero-posterior and left oblique positions respectively the right and left main pulmonary arteries may be seen to be enlarged. Enlargement of the right auricle is uncommon and is a late development usually associated with congestive failure. The left side of the heart both auricle and ventricle, was found to remain unaffected in uncomplicated emphysema and where the left ventricle was increased in size this was attributed to an accompanying hypertension. Auricular fibrillation was observed in one case only and the preservation of normal rhythm and the infrequency of failure account for the rarity of auricular enlargement. Congestive heart failure was found in only a small number of the cases and in half of these there was hypertension. The failure associated with uncomplicated emphysema is thus rare but the prognosis is bad the condition is in fact, usually a terminal one. Electrocardiography was of little help in diagnosis as signs of right heart involvement, such as right ventricular predominance (old terminology) were un-

common and close correlation with the radiological picture was impossible. The observations of Drs Parkinson and Hoyle, which are clearly illustrated by radiographs, indicate that cardiac changes elusive clinically, are to be recognized in emphysema only with the help of x-rays and provided they are sought in the right situations. Though these changes may not be of great significance from the functional point of view it is possible that when combined with those of hypertension, an association which is common, they may play an appreciable part in determining cardiac failure.

BOVINE TUBERCULOSIS IN THE NETHERLANDS

A Charlotte Ruys¹ has attempted to ascertain the frequency of tuberculosis of bovine origin in the province of North Holland. She used the cultural method and confirmed the identity of all bovine and some of the human strains by rabbit inoculation. From 204 sputa she isolated thirteen bovine strains. Inquiry showed that of the patients infected with the bovine type three out of 115 lived in Amsterdam and ten out of 89 in the country. Gastric contents from children were examined and strains isolated from 188 subjects. Among these, sixteen were of the bovine type. Sixty-six strains of tubercle bacilli were isolated from patients of all ages suffering from non-pulmonary tuberculosis. The samples examined included pus from cervical glands and joints, urine, ascitic fluid, cerebro-spinal fluid, and material from skin lesions. Of these strains eleven had the typical bovine characteristics. It will thus be seen that tuberculosis of bovine origin occurred with considerable frequency in the population examined. This is not surprising in view of the fact that 34 per cent of cattle slaughtered in Amsterdam in 1934 had tuberculosis lesions and 40.8 per cent of 11,000 cattle in North Holland reacted to the tuberculin test. Infection of human beings appears to occur chiefly by milk, and it is recommended that an active anti-tuberculosis campaign should be prosecuted in cattle and that all milk should be subjected to compulsory pasteurization.

The Council of the Royal Society of Arts has awarded the Albert Medal for 1937 to Lord Nuffield "for services to industry transport and medical science."

The Morison Lectures will be delivered before the Royal College of Physicians of Edinburgh by Dr R. G. Gordon on June 17 and 18 at 5 p.m. His subject is "The Neuro-Psychological Basis of Conduct Disorder."

The third annual conference convened by the Ex-Services Welfare Society will be held at 10 a.m. at the Grosvenor Hotel Victoria Station, S.W., on Friday, June 25 with Dr Edward Mapother in the chair. The subject for discussion will be "Control of the Incidence of War Neurosis" under the following heads: (1) The malingering before and after enlistment. (2) Elimination of the potential neurasthenic during training. (3) Treatment in the field.

CAPITATION FEE

REPORT OF COURT OF INQUIRY

Further to the proceedings of the Court of Inquiry into the remuneration of insurance practitioners, which were fully reported in the *Supplement* of June 5, the following communications have been received from the Ministry of Health

MINISTRY OF HEALTH
WHITEHALL S W 1
June 7 1937

Dear Sir

I am desired by Lord Amulree the Chairman of the Court of Inquiry into the remuneration of insurance practitioners appointed by the Minister of Health and Secretary of State for Scotland on May 5 1937 to forward to you for the information of the British Medical Association the enclosed copy of the Report of the Court submitted to the Minister of Health and Secretary of State for Scotland

Yours faithfully
E H PHILLIPS

The Secretary
British Medical Association
British Medical Association House
Tavistock Square
W C 1

National Health Insurance—Court of Inquiry into Remuneration of Insurance Practitioners

To the Rt. Hon Sir Kingsley Wood M.P. Minister of Health
and the Rt. Hon Walter E. Elliot, M.C. M.P., Secretary of State
for Scotland

WE, the under-signed, being the Court of Inquiry appointed by you in your minute dated May 5, 1937, have inquired into the matter mentioned in such minute and HEREBY REPORT that the amount of the capitation fee (per insured person per annum) on the basis of which the Central Practitioners Fund under Article 19 of the National Health Insurance (Medical Benefit) Regulations, 1936, and the corresponding Scottish Fund under Article 19 of the National Health Insurance (Medical Benefit) Consolidated Regulation (Scotland), 1929 should be calculated as from January 1, 1938, having regard to such changes as have taken place since 1924 in the cost of living, the working expenses of practice the number and nature of the services rendered by insurance practitioners to their insured patients and other relevant factors, and on the assumption that as from January 1 1938, employed persons under the age of 16 will have become entitled to medical benefit by virtue of amending legislation, but that the conditions would not impose any obligation upon the practitioner to issue medical certificates to these persons (such capitation fee not to include any payment in respect of the supply of drugs and appliances or any payment to meet the special conditions of practice in rural and semi-rural areas) should be nine shillings

E H PHILLIPS
Secretary to the Court.

AMULREE
T HOWORTH
D H ROBERTSON

June 5 1937

British Medical Association

PROCEEDINGS OF COUNCIL

WEDNESDAY, JUNE 2, 1937

A meeting of the Council of the Association was held on Wednesday, June 2, at the Association Headquarters in London. Sir KAYE LE FLEMING, Chairman of Council, presided, and the other members present were

Mr H. S. Souttar (Chairman of Representative Body) Mr N. Bishop Harman (Treasurer), Sir E. Farquhar Buzzard Bt (President), Dr H. G. Dain (Deputy Chairman Representative Body), Mr J. Armstrong, Dr J. W. Bone, Sir Henry Brackenbury, Prof. A. H. Burgess, Dr J. D. Commie, Mr W. McAdam Eccles, Dr C. E. S. Flemming, Dr T. Fraser, Mr J. L. Gilks, Dr L. G. Glover, Dr F. W. Goodbody, Dr R. G. Gordon, Dr C. O. Hawthorne, Dr J. Henderson, Dr J. Hudson, Dr J. Hunter, Dr I. Jones, Dr R. Langdon Down, Mr E. Lewis Lilley, Dr J. C. Loughridge, Dr P. Macdonald, Sir Ewen Maclean, Dr J. S. Manson, Dr O. Marriott, Dr J. C. Matthews, Dr J. B. Miller, Dr H. J. Miligan, Sir Richard Needham, Mr R. L. Newell, Dr L. A. Parry, Dr W. Paterson, Prof. R. M. F. Picken, Dr H. W. Pooler, Colonel A. H. Proctor, Dr H. Robinson, Dr E. H. Snell, Dr P. B. Spurgin, Surgeon Rear Admiral A. R. Thomas, Dr W. E. Thomas, Dr G. Clark Trotter, Dr S. Wand, Mr N. E. Waterfield, Dr W. Watkins-Pitchford, Dr W. N. West Watson, Dr W. G. Willoughby, Dr F. T. H. Wood.

Apologies for absence were intimated from the following

The President Elect, the Past President, Prof. R. J. A. Berry, Sir Crisp English, Dr E. R. Fothergill, Dr P. L. Giuseppe, Lieut.-Col. C. H. H. Harold, Dr H. C. Jonas, Dr J. R. Prytherch, Dr J. P. Shanley, Dr D. Lyon Stevenson, and Wing Commander H. M. Stanley Turner.

Preliminary Business

It was announced that the deaths had taken place of Dr Joseph Giusani of Cork and Dr George Parker of Bristol, former members of Council and the Chairman was authorized to forward letters of condolence. Later in presenting the report of the Journal Committee Dr Gordon referred with special regret to the death of Dr S. A. Kinnier Wilson, editor of the *Journal of Neurology and Psychopathology*, and the Chairman said that the Council would wish to express to Mrs Wilson its deep sympathy.

The Chairman was authorized to convey the congratulations of the Council to the members of the Association who have recently had honours conferred upon them by the King. He referred with particular pleasure to the conferment of the C.B.E. upon Dr James Perrins Major who was secretary of the Annual Meeting in Melbourne in 1935.

The Council unanimously agreed to recommend to the Representative Body that Dr S. Watson Smith of Bourne mouth, Past President, be elected a Vice-President of the Association in recognition of his exceptional services in connexion with the World Tour.

Dr Langdon Down was appointed representative on the Child Guidance Council and Sir Richard Needham was asked to attend as representative of the Association at the Imperial Social Hygiene Congress to be held at Westminster in July. An invitation was received from the Society for Cultural Relations between the Peoples of the British Commonwealth and the U.S.S.R. for a representative to take part in a tour of the medical institutions of Soviet Russia which the society is arranging. Dr Waterfield agreed to go as representing the Association.

A letter was read from the Indian Science Congress Association an organization of scientists in India run on lines similar to those of the British Association but in

cluding medical research among its sections. The letter stated that it was desired that about five delegates from the British Medical Association should attend the silver jubilee of the Indian body in January next. A few names were suggested, and it was left to the Office Committee to approach certain individuals in order to ascertain whether they would be willing to make the journey.

Sir Edmund Spriggs sent a report on the biennial conference of the New Zealand Branch of the Association at Wellington which he attended in February. He had delivered a message of good will to the conference from the Association in Great Britain, which was warmly received. Sir Edmund Spriggs added that the New Zealand Branch was in an active and flourishing state, the communications to the conference were of a high standard, and members of the profession from Great Britain were received and entertained most warmly.

On a proposal from the Northern Ireland Branch the Council agreed to vary the membership of the Emergency Committee for Northern Ireland, constituting it as follows: Dr James Boyd and Dr R. M. Beath, both of Belfast, with the president and honorary secretary of the Branch *ex officio*.

Annual Meeting, 1940

An invitation was forwarded from the Birmingham Branch to hold the Annual Meeting of the Association in Birmingham in the year 1940. Dr T. L. Hardy (immediate past president of the Branch) and Mr Fauset Welsh (honorary secretary) attended in support of the invitation.

Dr Hardy said that the invitation was a unanimous and a hearty one. In 1940 it would be twenty nine years since the Association last visited Birmingham, so that a visit was overdue. During the past five years a large hospital centre had been built in Birmingham in which it was hoped the voluntary hospital services of the city would ultimately be collected. Patients would be admitted for the first time next spring and by 1940 the hospital centre would be in full working order. There was every reason to believe that the civic authorities would welcome the Association in that year, and the University of Birmingham, through its Medical Faculty and its dean would do its best to co-operate in making the meeting a success. A further point to bear in mind, which had weighed with Dr Dain's colleagues and admirers in Birmingham was that in 1940 in all probability Dr Dain would be Chairman of the Representative Body and therefore there would be a special appropriateness in a meeting in Birmingham.

The Chairman thanked the representatives from Birmingham for their cordial invitation and after they had withdrawn Mr Bishop Harman moved that the invitation be accepted, and this was seconded by Dr Robinson and agreed to. The Liverpool Division was thanked for an invitation to hold the Annual Meeting in Liverpool in 1940 and was asked whether it would be possible to renew the invitation for a later year.

The Medical Secretary's Visit to India

The Council considered at some length a report by the Medical Secretary on his visit to India (December 1936 to March 1937) to investigate the conditions of medical practice and organization in that country. The report was a long document of more than one hundred numbered paragraphs and included a survey of existing medical and public health services with observations on their future development as well as an account of medical organizations in India. Dr Anderson on the presentation of the

report, referred briefly to the difficulties which he had experienced in putting on paper the views and impressions he had gathered during an extensive tour. He had done his best to bring forward some suggestions which would remedy a state of affairs that in his judgement ought to be remedied.

The report was discussed by Colonel Proctor, Sir Richard Needham, and others, and eventually it was agreed to refer it to an appropriate committee for consideration and for report to the Council with recommendations as to future action. The committee selected for this purpose was a joint one consisting of the Dominions Committee (the full title of which is the Dominions India Colonies and Dependencies Committee) and the Special Committee on the Reorganization of the Medical Profession in India. Power was given to the committee to co-opt, and the Chairman mentioned one or two names which might be usefully considered. On the motion of the Chairman the Council expressed its great appreciation to Dr Anderson for the labour which he had undertaken on the Association's behalf.

Scottish Health Services

Dr Miller brought forward a report from the Health Services Committee, which has considered the report of the Scottish Departmental Committee on Health Services. He said that neither the Departmental Committee's report nor the policy of the Association had a place for a full scheme of consultants and that question would have to be considered. As this was under review by another committee there was no need for him to say anything more about it at the moment, but the most gratifying feature of the Departmental Committee's report was that it was a most thorough and authoritative endorsement of the Association's health policy. In Scotland they would rather have a general medical service scheme applied to the whole kingdom than one limited to Scotland alone. When it came to sinews of war they had always found it an advantage to be associated with their affluent colleagues south of the Tweed.

Dr Hawthorne asked whether there was not included in the Departmental Committee's report a recommendation that an experiment should be made in compulsory notification of venereal diseases. It was certain that this matter would be raised in the British Social Hygiene Council on which the Association was represented and perhaps would be raised in a controversial form by the lay representatives a number of whom came from Scottish authorities. Had the Health Services Committee noted that particular proposal?

Dr Miller said that the majority of the Departmental Committee because of the seriousness of the effects of syphilis upon the race, were in favour of compulsory notification in much the same way as other infectious diseases were notified. They recommended however, that if it was deemed inexpedient to apply the system over the whole country powers should be given to the larger local authorities to adopt compulsory measures on an experimental basis. The Health Services Committee had considered the question but it was one which brought in very big issues and no observations were made upon it in the present report.

The Committee's report which will be included in the Supplementary Report of Council to be published in the next issue was approved.

Dr Miller added that the section of the report on Scottish Health Services dealing with the provision of consultant services had been referred to the Consultants and Specialists Group Committee which had already, he understood given it some preliminary consideration.

Payment of Medical Staffs

Professor Burgess for the Consultants and Specialists Group Committee, brought forward a recommendation

on the payment of medical staffs of voluntary hospitals. He pointed out that in its Hospital Policy the Association had urged that in respect of treatment given to 'contributing patients,' staffs should receive remuneration for such service either by salary payment for definite services and responsibility, honorarium or agreed contributions to a staff fund. Several resolutions had been passed urging medical boards to approach lay boards to press this matter and it was now felt that this section of the Hospital Policy should be urged directly upon boards of management of voluntary hospitals, and he moved a recommendation accordingly.

In reply to Dr Macdonald, who suggested that the matter might first be considered by the Hospitals Committee Sir Henry Brackenbury said that in the ordinary course such a recommendation would have been referred to the Hospitals Committee and presented to the Council in that way, but the Consultants Group Committee met at a later date than the Hospitals Committee, and inasmuch as this was a somewhat urgent matter it was thought desirable to bring it before the Council direct at the present meeting. It was merely a question of time and convenience.

Mr Souttar pointed out that this policy had again been endorsed in the recently published report of the Voluntary Hospitals Commission, and, emanating from such a source, it had made a great impression on the lay side of hospitals. He was aware of one important hospital where this matter was now being directly considered by the lay committee.

The recommendation was agreed to.

Voluntary Hospitals Commission

Dr Macdonald, chairman of the Hospitals Committee said that it was a matter of satisfaction to the Council to find that the report of the Voluntary Hospitals Commission so largely endorsed the policy of the Association, and that, with one exception, the points on which the Association had laid stress had been accepted. The report dealt with the co-ordination and co-operation of hospitals on which the Association evidence was very ably presented to the Commission by the Deputy Medical Secretary and the proposals had in general been accepted though it was true that the report did not go into great detail as to how co-operation was to be achieved. He regretted that the Commission was entirely silent on the question of beds being provided at hospitals where practitioners in general and general practitioners in particular could treat their own patients and he could not but feel that in this respect the Commission had missed an opportunity. Finally, it was a matter for regret that the Commission did not say explicitly that it was to the interest as well as the duty of local authorities to deal generously with the voluntary hospitals instead of in the grudging manner often obtaining at present. But he did not wish to end his report on this subject on any note of disapproval. It was a matter for congratulation that the Hospital Policy received such a large degree of confirmation. He added that Sir Henry Brackenbury who was acting chairman of the Commission at most of its sessions, had put an enormous amount of work into this investigation, and the Association and the medical profession were also specially indebted to Professor Sheen of Cardiff for his work as a member of the Commission.

Sir Henry Brackenbury took up a remark by Dr Macdonald on the Commission's suggestion with regard to the regional nature of the benefits of contributory schemes. It was well to make it clear that the word 'regional' in this connexion was contrasted not with national but with the individual hospital. The Commission thought there ought not to be a contributory scheme which admitted a patient to one single hospital but that a contributory patient should be able to receive benefit from any hospital in a region and it went on to say that so far as possible all the contributory schemes should be on those lines.

Public Health

In the absence of Professor Picken, Sir Henry Brackenbury introduced the report of the Public Health Committee. He stated that an inquiry had been received from a medical officer of health as to whether the Association was in general agreement with the recommendation of the Ministry in Circular 1550 that children between 2 and 5 years of age should be admissible to minor ailment clinics provided by local education authorities. The Committee had seen no objection to this proposal provided that the Association's existing policy in regard to the conduct and scope of such clinics was observed. But he thought they could now go further than this because, since that policy had been laid down, a large number of Public Medical Services had been set up, with the encouragement of the Association, and in areas where there was a public medical service there did not seem to be any real necessity for local government activity in this direction. He proposed, therefore, to add to this report the words, 'But the provision for minor ailments should be unnecessary in areas where there is a public medical service.'

The addition of these words was agreed to.

Sir Henry Brackenbury further drew attention on the report of this Committee, to the special investigation recently carried out by members of the medical staff of the Ministry of Health into maternal mortality in selected areas in England, the results of which were published in a White Paper (*Journal* May 8). A memorandum by the Council, published in the *Supplement* on the same date had been transmitted to the Ministry, and it was the policy therein contained which the Representative Body would be asked to endorse. He believed that the General Medical Council was making certain more or less informal representations to the Ministry which might result in the Ministry's proposals not being pursued further. Obviously it was out of the question to have one prescribed course for qualification, together with one *Register* kept by the General Medical Council, every registered medical practitioner having the right to practise medicine, surgery, and midwifery under the Medical Acts and at the same time to have another *Register* with other prescribed conditions and other criteria to be satisfied, set up by the Ministry of Health or, what would be even less satisfactory, by every local authority. It was therefore most desirable that at the Annual Representative Meeting some pronouncement should be made as to the conditions of a service of that kind which the profession would consider reasonable or unreasonable and in the last paragraph of the memorandum referred to a proposition was made to the Ministry of Health with regard to the compilation by local authorities of panels of practitioners to answer midwives calls and the conditions to which the profession would be prepared to accede were carefully set out.

The report of the Committee was approved.

Medico Political Activities

Dr Bone for the Medico-Political Committee brought forward a number of recommendations all of which were agreed to. The first related to approval of the draft scheme for the provision of medical attendance and treatment upon persons of moderate incomes above the national health insurance limits. This scheme will be found included in the Supplementary Report of Council to be published next week. The Council also approved the case which has been prepared for an increase of fees for medical witnesses in the courts and resolved that it be submitted to the Home Secretary who is to be asked to receive a deputation on the subject. It was further agreed that a parliamentary agent be employed to examine all Bills public and private provisional orders and the like introduced into Parliament and to bring to the Association's notice any proposals affecting or likely to affect the interests of the medical profession.

A suggestion made to the Committee by Dr H E Collier for the establishment of a diagnostic consultation clinic for diseases of occupation and industrial disability was reported to the Council. Dr Bone said that the Committee had come to the conclusion that a case had not been made out for the separation of occupational from other diseases for the purpose of clinical observation, and Dr Collier had been informed that the Committee did not favour the establishment of a consultation clinic on the lines suggested.

Dr Manson asked the Committee to reconsider its decision on this matter. While it might be true that a case had not been made out for the separation of occupational diseases so far as diagnosis was concerned, the clinic suggested by Dr Collier was designed to serve other purposes also—namely, the discovery of industrial factors in the causation of ordinary disease and ill health, and to recommend to the profession and to the workers and to industry in general any known preventive measures or safeguards against occupational disease. It seemed a pity that the Association should apparently stand in the way of prevention of occupational disease, and accordingly he moved that this part of the report be referred back to the Committee for further consideration.

Dr Hawthorne seconded the reference back.

Dr Bone said that this matter had been carefully considered by the Committee on two occasions on one of which Dr Collier was present, and the decision was taken after full regard had been paid to the details of his scheme which the Committee had before it.

The motion to refer back was lost.

Organization, Finance, and Office Arrangements -

On the motion of Dr Matthews, chairman of the Organization Committee, the new Bihar Central Provinces Delhi North West Frontier, and Sind Branches were included in the Indian group of Branches for the election of a member of Council. Dr Matthews said that the formation of these Branches had arisen as a consequence of the visit of the Medical Secretary to India.

The Chairman of Council was authorized to forward suitable letters to the following honorary secretaries who had relinquished office, and whose services were considered to be deserving of special recognition: Dr N R Dharmavir (Punjab Branch), Dr Pierce Grace (South Eastern of Ireland Branch), Dr G M Fitzgibbon (Bristol Division), Dr H C C Taylor (Derby Division).

Dr Dain presented a report from the Building Committee, which dealt with proposals for the building to be erected on the site of the northern extension in Upper Woburn Place, and with other matters. The report was approved.

Mr Bishop Harman reported that a cheque for over £300 had been received, representing the Association's proportion of the net profits arising on the general account of the National Ophthalmic Treatment Board. The loan made by the Association to the Board had now been fully repaid.

The Council again devoted considerable time to the discussion of a report from the Committee of Inquiry into Association office arrangements presented by Sir Kaye Le Fleming. It was agreed on the recommendation of the Committee that a layman of high educational standing be appointed to the staff of the Medical Department in order that he might assist with the preparation of memoranda and other documents. It was stated that the volume of work in that department was increasing rapidly, and still further expansion was in prospect.

Approval was also given to the appointments made by the Board of Directors of the *Journal* of Mr C W Francis as advertisement manager and Mr W H Moss as secretary to the Board. Consequent upon the reorganization of the Finance Department it had become necessary to create a new post in that department the duties of which would be mainly confined to the management of the

finances of the Association and the supervision of matters concerning the Association's properties. The Committee had appointed Mr W S Giles, who had already been for over twenty years in the Association's service, to the new post. It was also reported that Mr A Twelftree had been appointed head clerk in the Medical Department in place of Mr S Coulson, who, on a breakdown in health had been granted a retiring pension. Certain other matters affecting reorganization were decided.

Association Charities

In presenting the report of the Charities Committee Dr Robinson mentioned that a bequest of £50 had been received from the executors of the late Dr Isabella Aitken, who died in Nyasaland in January last. This was the first occasion on which the Charities Committee had received a bequest, and in recommending that it be assigned to the Sir Charles Hastings Fund for the augmentation of the capital of that fund his Committee thought it was desirable for intending testators to be assured that any bequests they made would be treated as capital and invested on behalf of one or more of the medical charities, they would not be spent as income. The recommendation was approved.

The Committee submitted a table of earmarked subscriptions to medical charities received through the Association over the twelve years 1925-36. The total amount was just over £60 000, the largest amount received in any one year being just over £7,000 in 1934.

Other Committee Business

A meeting of the Welsh Committee was reported. The Committee had discussed at length the advisability of continuing the Welsh Contract Practice Subcommittee particularly in view of the fact that recently an important contract practice dispute was dealt with centrally and not by the subcommittee. The Committee had agreed however that it was essential that the Welsh Subcommittee should continue to watch developments in relation to contract practice work in the Principality and to be consulted by the Divisions concerned, and it was reappointed for this purpose.

Dr Comrie, chairman of the Consultants and Specialists Group for Scotland, reported that the three medical corporations in Scotland had each been invited to nominate a direct representative on the Consultants Board. There was general approval of the scheme by the corporations, but some objection had been taken to the number of direct representatives proposed. He thought that if the number of direct representatives of each of the corporations were increased to two, the principal objection would be overcome. The Council agreed to allow the constitution of the Board to be amended so as to permit of this being done.

Sir Kaye Le Fleming reported that another meeting had been held of the Joint Committee of the Association and the Trades Union Council at which the Factories Bill and the rehabilitation of injured workmen among other matters had been discussed. The joint secretaries had visited Llanelli and had collected evidence for submission to the central committee whose findings the committee of management of the medical service at Llanelli had agreed to accept.

A report was made from the conference which had been called to consider the ethical machinery of the Association. A statement on the position will be included in the Supplementary Annual Report. The conference consisted of three of the standing committees to consider certain questions which had been raised concerning action to be taken centrally or by the Division in cases where members had applied for or accepted appointments the terms and conditions of which were contrary to the Memorandum of Recommendations. The report of the conference was approved.

Dr Paterson brought forward a report from the Dominions Committee which was approved. The matters with which it dealt will appear in the proceedings of that Committee in next week's *Supplement*.

A report was presented from the Journal Committee in which reference was made to the successful transfer of the composition of the *Journal* to the printing works of Messrs Eyre and Spottiswoode. Things had now settled down into a reorganized routine, and communication and other arrangements were running smoothly.

The Protection of Practices Committee submitted an interim report, in which it was stated that the Committee had defined the principles which should form the basis of any model scheme for the protection of the general practices of members of the profession joining H M Forces in a national emergency. The principles would be elaborated at a further meeting after which the Committee hoped to submit to the Council the draft model scheme which it had been instructed to prepare for issue to the Divisions.

The final act of the Council was to consider the draft Supplementary Annual Report to the Representative Body. Although at the outset of the meeting the Chairman, having in view the length and importance of the agenda, had warned the members that it might be necessary to sit late the business which included some rather lengthy discussions, was concluded at 6.30 p.m.

TESTING OF THE EYES

RECOGNITION OF UNQUALIFIED PRACTITIONERS

It is profoundly disturbing to express it very mildly, that the revised regulations dealing with the principal additional benefits under the national health insurance scheme continue to offend the medical profession. First the Dental Benefit Regulations, upon which we had occasion to comment adversely in September last (*Supplement* September 26 p 170) and now the regulations dealing with ophthalmic benefit. In the Dental Benefit Regulations we were dealing with an indirect method of attempting to regulate the fees of the medical profession (for the administration of anaesthetics), now a more serious position arises. The Minister proposes in the draft regulations laid before Parliament this week to give official recognition to the practice of sight testing by persons who are not registered medical practitioners. This would be virtually a considerable advance in the direction of statutory registration of sight-testing opticians, which has not only been vigorously opposed by the Association during the past thirty years but has also been reported upon unfavourably by successive Government Departmental Committees. We say with regret that these draft regulations are being published notwithstanding the concern that was shown by a weighty deputation from the British Medical Association received by the Minister personally as long ago as last November.

The position would have been bad enough if the considered and cogent arguments put forward by the members of that deputation had merely been ignored. It is aggravated by the fact that the regulations do not cede one single point which from the Minister's own statement the deputation was led to believe would be met. It is significant that, immediately following the deputation the Medical Secretary of the B.M.A. had occasion on receipt of a revised draft to express the Association's appreciation of the extent to which the draft regulations had been modified to give effect to the views expressed at the meeting with the Minister. This appreciation has proved to have been somewhat premature.

The new regulations propose to amend Article 25 of the Additional Benefit Regulations of 1930. Among the principal amendments are the setting up of a committee of representatives of approved societies and opticians and a power given to this committee to approve a scale of

charges for the provision of optical appliances 'which scale may include as a separate item any charge for a service rendered by an optician whether an optical appliance is supplied or not'. This committee will have the control of the arrangements which approved societies may make for the testing of the eyes and the supply of spectacles. It will issue the list of approved opticians, in which will be distinguished those who undertake sight-testing and those who do not, and it will also approve the form of "ophthalmic letter" informing the members of a society of the arrangements made by the society for the provision of the benefit and of their right to obtain the benefit otherwise than under those arrangements, and in particular, of their right to an ophthalmic examination. It will be observed that in the regulations there is a clear distinction drawn between a service and an ophthalmic examination. The regulations already define ophthalmic examination as meaning 'an examination of the eyes by a medical practitioner having special experience of ophthalmic work, and as including 'any advice or service in connexion with such examination and the issue of any necessary prescription'. "Service" quite clearly means sight-testing. In the existing regulations the expression which was used was 'a service rendered by an optician incidental to the provision of an appliance'. The new regulation, it will be observed, says that the scale may include a charge for a service rendered by an optician whether an optical appliance is supplied or not.

The reasons which have led the Association to offer the most uncompromising opposition to the recognition in a statutory document of the testing of the eyes by unqualified practitioners are well known to the profession, just as they are well known to the Minister and his advisers. There is here no narrow question of professional interests. We may remind our readers of some of the statements in a paper by the chairman of the Ophthalmic Committee of the British Medical Association in the *Supplement* of October 24, 1936.

For three successive years analyses have been prepared of the findings of a series of examinations of the eyes of patients who had obtained treatment through the medium of the National Eye Service organized by the National Ophthalmic Treatment Board. It has been alleged by some that the cases were for the most part, if not altogether simple refractions (whatever that may mean), and that they were scarcely related to serious disabilities or diseases of the eyes or of the body of the patient. The two previous analyses made it plain that these allegations had no basis in fact. Patients who came for treatment to the National Eye Service were found to present a large variety of eye conditions many of which were of such serious import as to constitute a threat to the sight of the affected patient if they were not correctly diagnosed and efficiently treated.

Against the findings of the ophthalmic medical practitioners—namely that of their patients no fewer than 34.6 per cent. had defects or diseases other than errors of refraction—there is this other fact that only 3 per cent. of such cases were notified by the opticians. The divergence of the figures is startling. There is ample evidence that the doctors' returns are correct. It must follow that the figures of the sight-testing opticians are wrong. The eye defects in the patients seen by them were either unrecognized or if they were recognized were not reported for medical examination.

And here is an extract from the Report of the Departmental Committee on the Causes and Prevention of Blindness, 1922.

"We are of opinion that it would be undesirable and a positive danger to the public for Parliament to pass any measure which might convey the idea that an optician who is a person qualified to provide glasses prescribed by medical men is further himself competent to examine the eyes of patients and to prescribe glasses for the correction of errors of refraction."

In conclusion, we may say at once that the members of the medical profession are well aware of the fact that a large proportion of the members of the community, having trouble with their eyes, go direct to the optician, who has had no medical training, to have their eyes tested. The figures quoted in Mr. Bishop Harman's paper show how much this is to be deplored, but the fact remains. There is no suggestion at all that there should be any attempt to coerce the public in their own interests to submit to a proper ophthalmic examination. What is in question is the action of the Minister (by a simple and apparently innocent device in a Departmental regulation) in giving statutory recognition to the examination of the eyes by men who have not had a medical training. It is more than the thin end of the wedge, and the medical profession, having failed to get satisfaction from the Minister, must see to it that the wrong which it is proposed to do by these regulations shall not be accomplished. The authorities are doing this presumably under sustained pressure from interested quarters and the damage to the eyes of insured persons may well be irrevocable.

GENERAL MEDICAL COUNCIL

Registration of Students

POSTPONED DATE OF OPERATION OF NEW RESOLUTIONS

The Council, with Sir NORMAN WALKER presiding, had before it on May 27 the report of the Education Committee on registration of students and the bringing into force of the resolutions regarding the curriculum passed by the Council a year ago.

Mr J B LEATHES, in introducing the report, said that the committee had now completed a full examination of the regulations of the Council with regard to the registration of medical and dental students with a view to removing discrepancies in practice. The conclusion at which it had arrived as a result of careful study of the practical operation of the existing procedure was that the Council might properly be advised to rescind the present regulations and substitute for them a series of recommendations. Hitherto the *Students Register* had been compiled from the forms of request for registration filled in by the students at the various schools, and in consequence had never been complete. What was now proposed by the committee was that the deans should send to the Council returns of all persons registered as medical or dental students in order that the Council might be in a position to compile an annual register of such students who had begun their professional status in each academic year. The Council would be content to rely upon these returns for such information as it might require as to the ages on which students started medical or dental study and the preliminary examinations in general education and additional examinations passed by students before admission to the schools. The Council would relinquish the policy by which the authorities of the schools and the licensing bodies had been encouraged to make the registration of students by the Council a condition precedent to their admission.

He accordingly moved the committee's recommendation that the present regulations so far as they related to the method of registration should be rescinded as from September 1 1938 and so far as they related to the conditions under which students were registered as from November 1 1938. He said that these two dates had been chosen on the one hand in order that deans entering students in October 1938 should send in their list beginning with the academic year 1938-9 and on the other hand that the new conditions of admission relating to age, general education, preliminary examinations and the like which would be affected by the Council's new resolutions in regard to professional education should not come into operation until those resolutions became effective.

He explained that originally the Council decided that the new resolutions should come into operation on January 1 next, but last session the Council adopted a recommendation of the committee that the date should be postponed to October 1, 1938, and the committee now recommended postponing for a further month, in order to give the schools a little more time to get into line with these changes. It would then be clear that the schools would be at liberty to deal with applications for admission in the first term of the academic year 1938-9, under the 1923 resolutions, and that applications for admission in any later term should be dealt with under the new resolutions adopted a year ago.

STANDARD OF GENERAL EDUCATION

The principal changes made in the recommendations to accord with the 1936 resolutions were that before registration as a medical student the applicant must be within three months of the attainment of eighteen years, and must have passed a recognized preliminary examination in general education and an additional examination conducted or recognized by one of the licensing bodies. The standard of general education remained that of university matriculation. The Council would also recognize as complying with these recommendations such examinations of universities in British India, the British Dominions and Colonies, and foreign countries as were accepted by any university of Great Britain Northern Ireland, or the Irish Free State as qualifying for entrance or matriculation. The standard of the additional examination in a subject or subjects of general education should be approximately that required in a subsidiary subject offered for the Higher School Certificate at the specified examinations. The school certificate in England, which could be taken at 16 or under might in certain conditions exempt from university matriculation, but provision was made at the schools for an examination at a higher standard—a Higher School Certificate for boys in later years. The certificate could be obtained either by taking three full subjects or two full subjects and two others at a somewhat less exacting standard. This latter standard might well have been in the minds of the Council as a standard for the additional examinations though the illustration might not be very helpful in Scotland where there was nothing to correspond with the Higher School Certificate system.

This change perhaps the most difficult of all the changes was not being brought forward without due cause. During the last fourteen years English schools had been teaching chemistry and physics to boys who intended to take up medicine, and a pernicious tendency had developed of allowing boys to pass their test in general education at 16—sometimes even earlier—and then setting them to study nothing but the principal medical subjects for the rest of their time at school. What was now suggested was an effort to combat that tendency and to draw the attention of masters and parents to the necessity of continuing the general education of students after they had passed the comparatively low standard of the school certificate. The committee had met in conference the deans of all save three of the London medical schools and they had unanimously agreed that this method could be worked so far as they were concerned.

With regard to dental students the committee advised the Council to recommend that these should be registered in the same manner and under the same conditions as medical students, but that applicants for registration might start their professional study as pupils of a registered dental practitioner instead of at a recognized dental hospital or school.

SUGGESTED POSTPONEMENT OF EFFECTIVE DATE

SIR HENRY BRACKENBURY declared himself unconvinced that the postponement of the operation of the new conditions from October 1 to November 1 1938 was either necessary or desirable. A year ago the Council had prescribed the new curriculum both preliminary and clinical

and had regarded it as a considerable improvement. It should not, therefore, be postponed longer than was fair and necessary to those who had already embarked upon some portion of their medical education. The effective date had already been once postponed in order to give the public and the secondary schools, from which most medical students were recruited, notice during two full school years of the alterations that might be necessary for the guidance of their senior boys and girls in the kind of curriculum they should take while at school or immediately afterwards. That notice had been ample. The only effect of postponing the change for one month would be to enable the authorities of medical schools to train the whole body of medical students who joined in 1938—for nearly all students entered in October—under the old instead of the new curriculum. In fact the recruitment of medical students under the improved conditions would be postponed for a year. The postponement would embarrass the schools themselves, for they might be conducting two different kinds of curriculum simultaneously, according to whether a student registered in October or in November.

MR R J JOHNSTONE also asked the reason for the change. His own faculty, he said, had spent a very strenuous winter session preparing for these alterations, which would not now come about for another year. He suggested that the same effect would be produced by a postponement to January 1 or even October 1, 1939.

MR LEATHES replied that when the new resolutions came into operation they would so far as they dealt with clinical years, affect not only students who entered for November 1, but all students only the conditions of entry after November 1 being affected. The committee had been advised that two years was not enough notice, and had thought it preferable to give what amounted practically to an additional year.

SIR HENRY BRACKENBURY asked whether a student who entered in October, 1938, and therefore under the old conditions, had not a right to claim registration afterwards because he had satisfied the old conditions, though not the new.

SIR ROBERT BOLAM suggested that such a question should be put to the licensing bodies. Sir Henry Brackenbury was not fully aware of the difficulties that beset the officers of medical schools when a new set of regulations was announced. The faculty at his own school had been bombarded by head masters and parents to know whether the pupils who had been under preparation for two or three years could sit in October 1938, under the old regulations or must prepare for the new regulations. To upset the medical curriculum entailed years of work for a licensing body in readjusting its arrangements. The postponement would mean that medical schools could, if they wanted, insist on pupils coming in under the new recommendations but gave them an option to do either. He hoped the Council would not embarrass the public and the medical schools by bringing the new conditions into force in October 1938, and forcing them to deal with many applications for exemption.

MR L P GANGEY said that the difficulties which Sir Robert Bolam had described were not experienced in all schools. His own school was quite ready to adopt the new regulations from the October date. If the change were postponed for a month it would probably cause trouble in the shape of applications from students who had entered under the old regulations to undergo the whole of the old curriculum. If the extra month were granted the Council should recommend that all students who entered during October 1938 should for the remainder of their course come under the new regulations.

DR D J COFFEY spoke in favour of the extra month. The raising of the age to 18 had been unexpected and the granting of this extra month would clear up some ambiguities and embarrassments. Dr J W BIGGER was of opinion that great confusion would be caused and students would go to the schools which offered the most

generous exemptions. If the notice given to the schools was not sufficient the correct procedure would be to hold back the new conditions for a further eleven months, until October, 1939.

After some further discussion a motion by Sir Henry Brackenbury to put the date forward until October, 1938, was lost by 20 votes to 6.

The British Pharmacopoeia

Dr DAVID CAMPBELL, in presenting the report of the Pharmacopoeia Committee, said that the report embodied a statement by the British Pharmacopoeia Commission concerning the scope of the next *Pharmacopoeia*. The Commission had reviewed the monographs of the present work and had made a survey of drugs which had been recently introduced or which were attaining increased use in therapeutics. It had also compiled a list of drugs which, through decreased use or doubtful therapeutic value, were no longer worth inclusion. The lists of proposed omissions and additions had been sent to the appropriate Government Departments and medical bodies, to the Governments of India and of the Dominions, and to officers of the Colonial Medical Service, with requests for criticisms and suggestions. Information had also been exchanged with the United States Pharmacopoeia Committee of Revision. It was proposed to revise the *U.S. Pharmacopoeia* by means of annual supplements, a plan which the Commission would watch with interest.

Public Health Diplomas

Sir GEORGE NEWMAN, chairman of the Public Health Committee, in introducing this report, referred to the new resolutions and rules submitted by the committee for diplomas and degrees in public health. Formerly the rules provided that candidates should produce evidence of having devoted a certain number of hours to the study of specified subjects, but the new rules laid down that a candidate should produce evidence that he had regularly attended a course lasting not less than a stated period. This change would be more convenient to the licensing bodies. The earlier provision that candidates must make twenty-four daily attendances of not less than two hours each at a fever hospital had been deleted as being too difficult to work. Candidates would now be required to show that they had attended for three months on the clinical practice of an approved hospital for infectious diseases. Of the twenty licensing bodies which had studied the draft rules only three had made substantial criticisms. The Royal Army Medical Corps and the Royal Institute of Public Health found difficulty in Rule 2, which provided that the curriculum must extend over a period of not less than twelve calendar months. The committee had felt that the old rules needed to be strengthened to exclude the part-time or somewhat transitory kind of training sometimes known as "night school" education.

Dr H. L. TIDY suggested that in the case of R.A.M.C. candidates this rule might be relaxed.

The revised rules were adopted without dissent. The date on which they are to come into operation is October 1, 1938.

Indian Medical Diplomas

It was reported that the Executive Committee had passed a resolution that holders of diplomas granted by the University of Calcutta on or after October 16, 1936, should be entitled to registration on the Colonial List. This followed a similar resolution passed by the Committee three months previously that holders of diplomas granted by the Punjab University on or after February 25, 1930, should be similarly entitled.

Sir NORMAN WALKER made a reference to the work of the recently established Medical Council of India in maintaining the standard of Indian University examinations.

Restoration After Removal at Own Request

The Council in November 1935, acceded to an application by Jean Braun, L.M.S.S.A. Lond., 1915, to have his name removed from the Register. It was now reported that on April 25, 1937, Mr Braun had applied that his name should be restored, and forwarded a statutory declaration and remittance in accordance with the Standing Orders relating to applications for restoration after non-penal erasure. The Executive Committee now reported to the Council that the Standing Orders did not expressly provide for the restoration to the Register of a name which had been removed at the practitioner's own request although in 1921 the Council was advised that it had an implied discretion to restore such a name and in fact it did actually make such a restoration. The committee recommended that the name of Mr Braun should be restored, and the Council acceded to the request, and afterwards considered *in camera* a report from the Executive Committee stating that counsel had advised that the Standing Orders dealing with the removal of names at the request of the practitioners themselves were *ultra vires* the Medical Acts giving the Council no such power. The committee was satisfied that the Council should recognize that its power to remove names of medical practitioners from the Register was limited to penal erasure under S. 29 and non-penal removal under S. 14 of the Medical Act, 1858.

The Council agreed with the recommendations of the Executive Committee that the Standing Orders relating to erasure at the practitioner's request should be deleted.

Election of Committees

The nominations of the Branch Councils for the following committees were approved:

Education: Sir R. Bolam, Sir F. Buzzard, Dr. Dain, Mr. Edington, Mr. Hey Groves, Dr. Kidd, Mr. Leathers, Dr. Moorhead, Mr. Sinclair, Dr. S. Smith, Dr. Tidy, Dr. Waterston.

Examination: Dr. Brocklehurst, Dr. Campbell, Dr. Coffey, Mr. Eason, Mr. Gamgee, Mr. Johnstone, Sir W. Langdon Brown, Dr. Mathew, Mr. Miles, Sir T. Myles, Dr. Stopford, Dr. Wall.

Public Health: Dr. Bigger, Dr. Bone, Sir H. Brackenbury, Dr. Cathcart, Sir Kaye Le Fleming, Mr. Bishop Harmon, Dr. Kidd, Dr. Magennis, Sir G. Newman, Mr. Ritchie, Mr. Sheen, Dr. S. Smith.

The following were elected to Penal Cases Committee: Sir R. Bolam, Dr. Coffey, Mr. Eason, Mr. Miles.

SIR THOMAS NEILL

It is difficult to think of national health insurance without Sir Thomas Neill, whose death on May 31 at the age of 81 we have to record. When the question of administering this new vast scheme arose in the autumn of 1911, and it was found that it would be quite impossible to launch the scheme without the aid of the great industrial societies, Sir Thomas Neill was called in by Mr. Lloyd George to help Sir Robert Morant in his task. Sir Thomas only held the post of Commissioner for a few short years but in common with others who went through the hurly burly of it all he must have looked back on those years as being the most strenuous and exciting in his career. He was indeed a tower of strength and after leaving the Insurance Commission to become Chairman of the National Amalgamated Approved Societies he continued to work in close and friendly collaboration with all parties concerned with the administration. He was a very friendly and indeed a lovable man whether he was on the same side of the table or not. No conference or important gathering where in particular approved societies and the medical profession have met together has been complete without him. Indeed it is not too much to say that the way in which the societies and the doctors have come more and more together and learned to see each other's point of view is attributable in large measure to Sir Thomas Neill.

Annual Meeting, Belfast Over-seas Representatives

Dominions and Colonial representatives, delegates, and members will be warmly welcomed at the Annual Meeting to be held in Belfast in July. All those from over seas who contemplate attending are asked to notify the Secretary B.M.A., Whitla Medical Institute College Square North, Belfast, as soon as possible, saying whether they will be accompanied, and, if they require accommodation, whether they desire private hospitality if such should be available. It would also facilitate matters if they would state the dates of arrival at and departure from Belfast.

Annual Dinner and Dance

The demand for seats at the Annual Dinner this year has been such that the Dinner Committee was faced with all the seats being booked on June 1. This function has proved to be so attractive in this year's programme that for several weeks past every post has brought applications from all over England, Scotland, Wales, and Ireland. Additional tables have however been added this week, bringing the total number of seats available to 1300. By the time this notice appears most of those additional seats will probably have been booked and the committee therefore proposes to make a waiting list from which vacancies, due to cancellations or other causes will be filled in order.

It has been officially announced that the Governor of Northern Ireland (the Duke of Abercorn) will be present at the dinner.

Mr S Coulson

It will be noted from the Proceedings of Council that Mr S Coulson chief clerk of the medical department a much valued member of the staff of the Association has been retired for reasons of ill health. Mr Coulson has been in the service of the Association for thirty years and is well known to many members of the Representative Body and of the Panel Conference of Local Medical and Panel Committees. He acted as clerk to the Council from 1919 and to the Insurance Acts Committee from its inception in 1912. Of Mr Coulson's many first rate qualities perhaps the most notable are a remarkable memory and an extraordinarily quick grasp of essentials. His knowledge of the Association's activities was equalled by that

of few others, and his assistance in the work of the Insurance Acts Committee was invaluable because of his unrivalled knowledge of the intricacies of the Medical Benefit Regulations under the National Health Insurance Acts. In Mr Coulson's enforced retirement the Association loses a most loyal servant, and he carries with him the best wishes of all who knew him.

Branch and Division Meetings to be Held

ABERDEEN BRANCH—At Glen O Dee Hotel Banchory Wednesday June 16 3.45 p.m. Annual meeting. Consideration of Annual Report of Council election of officers, etc.

HERTFORDSHIRE BRANCH EAST HERTFORDSHIRE DIVISION—At Canons Hotel Ware, Thursday, June 17, 8 p.m. Chairman's inaugural address.

In the report of the proceedings at the Court of Inquiry into the insurance capitation fee which appeared in the Supplement of June 5 Drs J A Brown and C F T Scott were mentioned as among those who represented the Insurance Acts Committee in the presentation of its case. Although Drs Brown and Scott were present as interested observers during the proceedings they took no part in the actual presentation of the Insurance Acts Committee's case.

ANNUAL REPRESENTATIVE MEETING, BELFAST, 1937

The Annual Representative Meeting of the British Medical Association will be held in the Assembly Hall, Assembly Buildings, Fisherwick Place, Belfast, on Friday, Saturday, Monday, and Tuesday, July 16, 17, 19, and 20, 1937

RESOLUTIONS BY DIVISIONS AND BRANCHES FOR THE REPRESENTATIVE BODY

DENTAL BENEFIT REGULATIONS

Motion BY SOUTHPORT LANARSHIRE, AND NEWCASTLE-UPON-TYNE That (with reference to para 83 of Annual Report of Council) the Representative Body disapproves of the adoption of a sliding scale for the administration of general anaesthetics for the removal of teeth and that the policy of the Association as previously expressed be adhered to

MEDICAL REGISTRATION

Motion BY NEWCASTLE-UPON-TYNE That the Representative Body urges the Council of the British Medical Association to suggest to the General Medical Council that all persons after passing the qualifying examination should complete six months in an approved practice or dispensary before being registered to practise medicine or surgery, or medicine and surgery

FINANCE

Motion BY NEWCASTLE-UPON-TYNE That (with reference to para 23 of Annual Report of Council) the Representative Body views with some misgiving the steadily increasing expenditure of the British Medical Association and trusts that every endeavour will be made to limit this expenditure so that, at some future date the subscription could be lowered from three guineas to its original amount of two guineas, thereby ensuring an increase in membership and a consequent strengthening of the Association's influence on behalf of the profession

THE GENERAL PRACTITIONER AND MIDWIFERY

Motion BY NEWCASTLE-UPON-TYNE That (with reference to the Addendum to the Annual Report of Council relating to maternal mortality Supplement May 8 1937, pp 269-71) the Representative Body views with growing anxiety the tendency to deprive the general practitioner of the practice of midwifery and its associated ante natal work

GENERAL PRACTITIONERS COMMITTEE

Motion BY MANCHESTER That a Standing Committee to be known as the 'General Practitioners Committee' be formed the members of the Committee to be confined to those members of the Association who are predominantly engaged in general practice and whose duties and powers would be to consider matters specially affecting general practitioners

HEARING AIDS

Motion BY EAST KENT That the Council be instructed to inquire into the question of hearing aids with particular reference to the manner in which suitable types should be supplied to deaf persons

DISPENSARY MEDICAL OFFICERS IN NORTHERN IRELAND

Motion BY BELFAST That the Representative Body is of the opinion that the present regulations in Northern Ireland regarding the services of dispensary medical officers especially in the certification of mental patients and remuneration for assistance in difficult maternity cases require (drastic) alteration

Forsyth—At Hong Kong on May 15 to Dorothy wife of Surgeon Lieutenant Commander A. N. Forsyth Royal Navy 3 daughter

DEATH

SHIRLEY WEBB—C. H. Shirley Webb M.S. F.R.C.S. died at 11 Addeney Hospital on June 1 1937

CONFERENCE ON MATERNITY AND CHILD WELFARE

The seventh English speaking Conference on Maternity and Child Welfare was held at the British Medical Association House, London, from June 1 to 3. Over 600 delegates were appointed, many of them from distant parts of the Empire and from the American continent and among those who presided or took part were Dr R E Wodehouse, Deputy Minister of the Department of Pensions and National Health, Canada, the Hon G F Gaha, Minister of Health of Tasmania, and Dame Enid Lyons, wife of the Prime Minister of Australia.

Review of Progress by Minister of Health

The conference was opened by Sir KINGSLEY WOOD the Minister of Health, who gave a review of recent progress in the field of maternal and infant care. The rate of maternal mortality in this country had not been specially high, fluctuating around four deaths per 1,000 births, and the number of deaths due to child bearing was less than 8 per cent of all deaths of women of child bearing age. The disappointing feature was, however, that notwithstanding much intensive effort, the death rate had not been substantially lowered, and a proportion of the maternal deaths were undoubtedly preventable. The Ministry was watching with close attention the provisions for the fuller clinical training of medical students in obstetrics and the new provisions for the training of midwives also the improvements in the science and technique of midwifery. The number of ante natal clinics had increased from 1,253 in 1931 to 1,672 in 1936 and the number of expectant mothers attending these clinics last year was 298,000 representing just over 48 per cent of the total of notified births. With a further number of women examined by local practitioners elsewhere than at the clinics but under arrangements made by local authorities the proportion was brought up to over 50 per cent. The number of beds subsidized in 1936 by local authorities was 8,626, comparing with 7,123 in 1931, and the number of women admitted to this accommodation had increased from 97,860 to 149,547. Many inpatient maternity units, particularly in hospitals taken over by county and county borough councils had been modernized and extended. The Minister then went on to make the gratifying announcement that the number of maternal deaths per 1,000 live births in 1936 was 3.81 comparing with 4.11 in 1935, the lowest rate recorded since 1922.

The Midwives Act

All these measures said Sir Kingsley Wood, had received a powerful reinforcement from the new Midwives Act. That Act enabled the midwifery service to be provided in one or both of two ways by the direct employment of salaried midwives by the local supervising authority or by arrangement with voluntary associations. The greater number of county councils were making arrangements with the county and district nursing associations while the authorities in urban areas were more commonly providing for the direct employment of midwives or adopting a combination of the two methods.

Finally Sir Kingsley Wood referred to the special investigations into maternal mortality carried out by a number of the Ministry's medical officers together with Sir Conway Berkeley during the last two years. The inquiry had been made in six administrative areas in 1935 and 1936 while maternal mortality had been above the average. The report had disclosed many interesting facts.

All this was to be that no elaborate statistics were available on the incidence of abortion the investigators had been able to get on to the practice of artificial abortion which was increasing and was on a scale which was a serious maternal danger.

Infant mortality continued at a low level. During the last three years—1934-6—the rate for the first time had been under sixty per thousand births. This compared with rates of seventy and upwards ten years ago.

Parents and Psychology

Only the most cursory review of outstanding discussions in a three-day conference can be given. Dr ERIC PRITCHARD spoke on the education of parents, and urged that the teaching of mothercraft should have in view the protection of infants from the risk of infection. Dr URSULA COX stressed the value of group teaching of parents, pointing out that a given subject could be discussed in much more detail and with much more emphasis and assertion in a group than with a single individual. Dr STELLA CHURCHILL protested against the clock as too rigid a dictator in infant welfare. Mothers were taught to say, 'It is not yet feeding time, the baby must be kept screaming for another half-hour,' or they must lie awake in the early morning and listen to its crying until the clock struck six. The pendulum had swung too far from the time when infants were fed every two hours whether they wanted it or not.

Dr J A HADFIELD gave what amounted to a lecture on preventive psychology. He described the psychological development of the young child at different ages, and insisted that every age should have respect paid to it. The self-assertiveness of age 2 would develop into the will power of age 4. The parent who forced the child of 5 to be sociable might be attempting something unnatural in view of the fact that the child was then developing its ego. He spoke of the importance of investigating the terrors of young children, the fundamental cause was the deprivation of love and affection. He did not agree with Freud as to the sexual basis, but it was not to be doubted that protective affection was the primary need of every child, and if deprived it developed fears and anxieties. Neurotic disorders might be traced back to the first three or four years of life.

Dr MARGARET LOWENFELD suggested that there be included in the ordinary training of all nurses midwives and children's doctors lectures devoted to the explanation of the psychological aspects of maternal and infant care and that all ante natal and post natal nurses and midwives should have lectures on the emotional aspect of pregnancy, labour, and lactation.

Nutritional Problems

A discussion on nutritional problems in relation to mother and child in which the economic question would obtrude itself in spite of the earnest efforts of the chairman Dr Wodehouse the Canadian Minister to keep it out) was opened by Dr ROBERT McCANCE who confessed that despite the work done on the subject during the last twenty years there was still much obscurity. But the civilized world now had at its disposal a good deal of knowledge about nutrition sufficient to enable it to be said that millions of human beings certainly at some periods of their lives, were not adequately nourished and enough theoretical knowledge was also available to formulate a proper diet. Dr R C JEWESBURY dealt with nutrition during pregnancy and lactation and pleaded for a wider understanding of dietetics and food values in order to minimize the nutritional problems in relation to parent and infant.

The subject of preventive work for cripples and invalid children was developed by Dr BERNARD SCHLESINGER who gave an account of experiences gained during the last ten years at the Children's Heart Hospital, West Wickham, also a cheerful outline of the results of a follow up system among rheumatic children. Mr E S EVANS discussed problems requiring further attention in the prevention of crippling. These included the provision of clean safe milk, the exhibition of modern nursery schools and play centres and the general improvement of

social and hygienic conditions. A session was devoted to maternity and child welfare in backward regions, and gave an opportunity for an exchange of experiences by visitors from different parts of the Colonial Empire. Dr MARY BLACKLOCK described the conditions of maternity and child welfare work in Sierra Leone, and Dr MABEL BRODIE in Malaya.

This was the seventh English-speaking conference, and Dr G F MCCLEARY, chairman of the Association of Maternity and Child Welfare Centres, who presided over the first session, recalled the origin of the movement. It sprang from the Congrès Internationale des Gouttes de Lait held in Paris in 1905 the first international gathering devoted to maternity and child welfare, and attended by representatives of three British local authorities—Battersea, Glasgow, and Huddersfield. These representatives were so much impressed with the enthusiasm with which problems of infant welfare were being tackled in France that they determined to initiate a conference in London, and under the presidency of Mr John Burns, then President of the Local Government Board, it was held in the following year. At the third national conference in 1912 the National Association for the Prevention of Infant Mortality was formed, and this has since organized twenty national conferences and six conferences of English-speaking peoples.

REHABILITATION AFTER ACCIDENTS

REPORT OF COMMITTEE

In April, 1936, an inter-departmental committee was set up by the Home Secretary, the Minister of Health, and the Secretary of State for Scotland to inquire into the arrangements made in this country for the restoration of the working capacity of persons injured by accidents. The decision to appoint this committee was taken after consideration of the report issued by the British Medical Association early in 1935,¹ which made suggestions for improving the organization of present arrangements for the treatment of fractures and drew attention to the importance of the industrial aspects of this question. The committee's terms of reference are

To inquire into the arrangements at present in operation with a view to the restoration of the working capacity of persons injured by accidents and to report as to what improvements or developments are desirable and what steps are expedient to give effect thereto regard being had to the recommendations made in the report issued by the British Medical Association in February 1935 on fractures.

The medical members of the committee of which Sir Malcolm Delevingne is chairman, are Dr Muriel Bywaters, Mr W A Cochrane, Dr T Ferguson, Mr E W Hey Groves, Dr J F E Prideaux, Mr H S Souttar and Mr A C T Woodward.

Treatment of Fractures

It was apparent from the B.M.A. report and from information available from other sources that the question of the treatment of fractures was of special urgency, and for this reason with the approval of the Ministry of Health the committee decided to deal first with this part of the subject.

The committee issued an interim report at the end of last week. Introducing a survey of the present position it says

The recommendations in the report issued by the British Medical Association laid down certain principles both of

British Medical Journal Supplement February 16 1935. Reprinted in pamphlet form Price 4d., or 4d. post free and obtainable from the British Medical Association, Tavistock Square, W.C.1 or through any bookseller.

Interim Report of the Inter-Departmental Committee on the Rehabilitation of Persons Injured by Accidents 1937 H.M. Stationery Office (4d.)

organization and of treatment. The principles of organization may be summarized as concentration of cases in one department under a single control, continuity of treatment and supervision by that department until rehabilitation—that is restoration to working capacity—has been effected to the fullest possible extent and a system of records of cases which will permit the history of each case to be followed from start to finish and the final results ascertained. The principles of treatment aim at securing exact reduction of the fracture, fixation in correct position and immobilization of the broken part, and active movement from the earliest possible moment of the uninjured parts of the limb to prevent wastage of muscles and stiffness of joints. We were given to understand that these general principles were accepted by the Government Departments concerned, and that the object in view was the provision throughout the country of fracture services which would place within the reach of every injured person the benefits of the improved methods of treatment, with the threefold result of mitigating suffering, reducing the period of disablement and the loss of working and earning power and securing wherever possible complete restoration of working capacity.

Organization of Fracture Clinics

The report outlines a scheme for a "model clinic" for the assistance of those engaged in the consideration of such proposals. The importance of unified control and the constant supervision and direction of all cases by a visiting surgeon specially appointed is emphasized. In view of the onerous nature of his duties it is recommended that the surgeon in-charge should have an honorarium.

The committee concludes that the provision of a net work of fracture services covering the whole country will call for careful planning to meet local needs and conditions. The co-operation of local authorities, hospitals, the medical profession, and of employers and workers organizations will be necessary, and in some areas is already being secured.

The report records that the number of fracture cases treated annually in the hospitals of England, Wales, and Scotland is well over 200,000. The committee received information from 825 hospitals in the three countries of which 724 were voluntary and 101 municipal. In fifty-nine of these there are special fracture departments under a single control, ensuring continuity of treatment until the patient is restored to work. These fifty-nine hospitals treat about 50,000 cases annually. The establishment of new fracture services and clinics, the committee understands, is also being considered in many quarters.

Circular to Local Authorities

Copies of the committee's interim report have been forwarded to county councils and county borough councils in England from the Ministry of Health with a letter (Circular 1632). This points out that the main purpose of the report is to make known the lines on which fracture clinics should be organized, equipped and staffed, and the relations between these clinics and the cottage hospitals etc. which serve outlying areas. The Minister trusts that if any council proposes to establish a clinic for the treatment of fractures under either the Public Health or the Poor Law Acts reference will be made to the detailed scheme advised by the committee, which is ready to assist in the consideration of any difficulties that may be presented in the application of the scheme by local circumstances.

D. Sibila (*Polichinico Sez. prat.* April 19, 1937 p. 772) from observations on forty cases of relapsing fever among the coloured troops in Addis Ababa came to the conclusion that the only type of spirochaete found among them was identical with Obermeier's spirillum in its morphological features, mode of transmission by lice and pathogenicity for animals.

Reports of Societies

BEJEL—THE SYPHILIS OF BEDOUIN CHILDREN

At a meeting of the Royal Society of Tropical Medicine and Hygiene on May 20, with the president, Sir ARTHUR BAGSHAWE in the chair, a paper on bejel—the syphilis of Bedouin children—was read by Dr ELLIS H HUDSON

Dr Hudson said that bejel was the Arab name of a spirochaetal disease found among the semi nomad villagers of the Middle Euphrates, it had also been recognized on the Lower Euphrates and along the Tigris and among the nomad Bedouins of the Syrian Desert. The bejel type of syphilis—operating under the epidemiological triad of widespread community infection, childhood acquisition, and general lack of treatment—was present in many other regions of the world. A thorough study of this clinical entity, however, had hitherto been handicapped by inevitable confusion with either venereally acquired syphilis or yaws, or with both.

The location of the Middle Euphrates on the thirty-fifth degree of latitude north—far from the accepted endemic regions of yaws—the remarkable isolation of this region and the absence of sexual promiscuity and venereal disease among the Bedouin villagers, had presented an opportunity for the study of bejel. The essential feature which distinguished it from venereally acquired syphilis was that bejel was usually contracted in childhood. Children of the village communities constituted the reservoir and the source of contagion of the disease. 60 per cent of the adults had acquired it in childhood and a majority of the remainder contracted it from children, often their own later in life. In a dirty, careless, poorly clad, closely huddled and untreated population the facilities for transfer of the spirochaete by non sexual contacts were innumerable, especially among the children. Less than 1 per cent of the adults acquired the disease through sexual intercourse, 75 per cent of the general adult population stated they had had bejel, and about 75 per cent had positive serological reactions. Surveys showed that 90 per cent of the adults were affected. That bejel was a treponematoses was established by the character of the early and late lesions, the phenomenon of relapse, the quality of latency, the uniform presence of a spirochaete indistinguishable from *Treponema pallidum* the positive precipitation and complement fixation reactions, and the favourable response to antispirechaetal drugs.

Cure of the individual patient was not a practical objective in bejel. The aim should rather be to eliminate the disease from the community by preventing the development of new cases and this could be accomplished by sealing up the infection already present. This objective could be secured by the use of bismuth without risk to the patient and in a time schedule adapted to the temperament of the primitive patient. Bismuth was less toxic and more effective than mercury. It was more suitable to the conditions of bejel than the arsenicals and easier of administration, less hazardous to the patient, and much cheaper. Bejel resembled yaws in non venereal childhood acquisition, community wide dissemination, lack of diagnostic value of the patient's own statement regarding infection, absence of chancre immunity, multiplicity of the skin lesions, predilection for the skin and the bones, relative escape of the eyes, the cardiovascular system, the central nervous system and the viscera, absence of constitutional disturbances congenital transmission, and the failure of prophylactic failure to produce immunity and sterilization and in many families and villages and the presence of congenital yaws, articular rheumatism and other degenerative changes, both bejel and yaws being a part of the same disease entity. The only difference between bejel and yaws was the age of acquisition and the fact that bejel was the

drug of choice. On the other hand, bejel resembled syphilis in its constant involvement of the mucous membrane, in the complication of alopecia in many of its general pathological aspects, and in its extra-tropical geographical location. In general, bejel seemed to occupy an intermediate position between yaws and syphilis and a clear-cut differential point was lacking. The view was defensible that the three forms of treponematoses had an identical aetiological basis and that their differences might be explained on epidemiological grounds if the influence of all environmental factors were known. To assume that bejel was yaws would obviously be of no help in this general problem, and it might be noted that physicians in the bejel region had generally assumed that it was the acquired syphilis of childhood.

Bejel had the character of an ancient disease, and probably presented a contemporary picture of syphilis as it existed in ancient times. The search in ancient medical literature for references to syphilis as a venereally acquired disease might therefore be aside from the point. Though 90 per cent of the adults of the Bedouin village were syphilitic, they did not have venereal histories or lesions, nor the visceral pathology associated with venereally acquired syphilis. Possibly references to a childhood disease resembling bejel might be found in ancient medical writings. In bejel the treponema was allowed to go its own way, unrestrained by human intervention. From the biological standpoint bejel was syphilis in its 'lowest terms,' the archetype of this treponematoses. That syphilis had ceased to be a childhood disease and assumed a venereal character was not due to any tropism of the spirochaete towards the genitalia but to the delimitation of its activities to a narrow field of bodily contact by the environmental conditions of civilized life. The clinical picture and the pathology of venereally acquired syphilis were related to the epidemiological fact that it was linked with sexual intercourse. The contribution of bejel to the knowledge of syphilis was twofold. It gave a clear picture of syphilis biologically unrestrained and free from human interference. It showed also that syphilis when propagated under the epidemiological conditions of yaws approached closely to yaws in clinical character, immunology, and pathology. This was strong evidence in favour of the essential identity of syphilis and yaws. A definite conclusion on this point waited upon further investigation of syphilis, bejel, and yaws in the fields of epidemiology, pathology, and animal experimentation.

Discussion

Professor BLACK LOCK pointed out that some years ago he began to doubt the validity of the criteria by which yaws was differentiated from syphilis. These views when published were much criticized. Dr Hudson's work showed clearly that this syphilis in children—bejel—was not transmitted congenitally to the next generation and also that syphilis could not be distinguished from yaws simply on account of the genital site of the primary lesion in syphilis. Two questions arose in regard to modern treatment. First would patients with yaws treated sufficiently to render the condition subclinical develop nervous sequelae later on? Secondly would children cured of their yaws be susceptible to adult syphilis as they got older?

Colonel L. W. HARRISON was impressed by the similarity between Dr Hudson's experience and that of others like Dr MacQueen who in Palestine had described very similar facts some three years ago. MacQueen mentioned in his bibliography that the earlier workers in Dalmatia, Croatia, Bosnia, Herzegovina and Asia Minor had described much the same state of affairs in their countries. Colonel Harrison emphasized the importance of clearing up the difference between venereal syphilis and yaws, and the place of bejel in the general picture of the central nervous system and the place of bejel in the pathology of the

and spinal cord Kemp in Chicago concluded that inadequate treatment did not promote the incidence of neuro-syphilis. On the other hand, he knew that the development of meningo-vascular syphilis was promoted by inadequate treatment with arseno benzol. The absence of miscarriage was interesting he suggested that this was due to the mothers having acquired bejel in childhood. He also suggested that in bejel there might be a chancre on the tonsil or in the mouth, and asked whether unilateral enlargement of the submaxillary glands or of the submental glands was present.

Dr H. S. STANNUS said that, although Dr Hudson's observations formed a most valuable addition to the clinical knowledge of syphilis, he doubted if bejel was a link in the syphilis-yaws chain. Syphilis was not a purely venereal disease, Stokes had found, in some 20 per cent. of males and in 36 per cent. of females, that the primary chancre was extra-genital. One should speak of venereally acquired syphilis and non-venereally acquired syphilis, not of venereal syphilis and non-venereal syphilis, as was common custom. He was satisfied that the skin lesions of bejel were quite distinct from those of yaws. The fact that the mucous membranes of the mouth and nasopharynx were always affected in bejel was most significant in regard to its relation to syphilis, since true lesions of the mucous membranes never occurred in yaws apart from "spreads" across muco-cutaneous junctions and some few instances due to direct inoculation. Adenopathy in bejel was generally not localized, as in yaws. Alopecia did not occur in yaws, while the positive Wassermann reaction in the cerebro-spinal fluid of bejel patients was very significant. In his opinion syphilis, including bejel, always presented characteristics distinguishing it from yaws.

Dr H. M. HANSCHALL was convinced that yaws was not syphilis. In the case of bejel, infection might be transmitted by "droplet spray". The spirochaete in this disease did not produce a primary chancre and did not get through the choroid plexus into the central nervous system or traverse the placenta. One was therefore forced to conclude that it was a different spirochaete.

Dr P. H. MANSON-BAHR expressed the opinion that, though syphilis diverged from yaws, they were originally the same disease. Dr WILLIAM CORNER referred to his experience of bejel among the semi-nomadic Arab cultivators in Iraq, pointing out that practically 100 per cent. had mucous patches in the mouth at one time or another. Another common condition was leucoplakia of the cheeks and mouth. In his opinion venereal syphilis in the towns in Iraq was milder than European syphilis. Dr C. C. CHESTERMAN differed from Dr Stannus in considering that the lesions of bejel reminded him of yaws rather than of syphilis. He had observed 30,000 cases of yaws in fifteen years and had seen in that series practically every lesion described by Dr Hudson in his paper. He has never seen a case of nervous system involvement in inadequately treated yaws patients.

In his reply Dr HUDSON dealt specially with the question of treating the individual or of dealing with the disease as a community problem. Only a certain proportion of the community had open lesions at any one time and if these were healed the number of new cases would rapidly decrease. Provided the disease manifestations were made subclinical and the individual rendered non-infectious he would take the risk of inadequately treated individuals developing neuro-syphilis. In yaws one started with the assumption that the disease could be cured by means of two or three injections of arsenical preparations and a few injections of bismuth whereas they were taught that syphilis could not be cured in less than eighteen months continuous treatment. This was not practical in village or desert nomads. He had observed no evidence of primary chancres in the mouth or throat though he agreed there must be a primary lesion somewhere.

THE PSYCHOTHERAPY OF DELINQUENTS

A SURVEY OF THE YEAR'S WORK

The Institute for the Scientific Treatment of Delinquency held its annual general meeting at the house of the Pharmaceutical Society, with EARL DE LA WARR in the chair, who reported that the Institute had been making steady progress during the past year. Its importance was not to be measured solely by the number of cases it had treated, but also by the tremendous influence which it could exert on general thought in regard to delinquency. Any alteration in the present prison system with its tyranny and hopelessness, must provide a practicable and properly thought-out alternative. The Institute was helping to mould the emotional revolt of the community into a constructive form. He pleaded, however, for a psychological approach not only to criminal but to social problems in general. Possibly the politicians of the future might have to undergo an examination to determine their psychological fitness to administer the nation's affairs!

Dr DENIS CARROLL outlined the work which had been done especially at the Institute's clinic, during the year under review. The staff had recorded several cases as 'cured,' meaning that treatment had been stopped and the patients would in all probability commit no further offences. Other cases had been discharged improved—"improved," not as criminals but as citizens. A frequent criticism of the work was that it merely taught criminals to avoid detection. This was not true. On the contrary, once treatment had progressed a certain distance the psychologist could be fairly certain whether the patient was intending to commit further offences or not. The staff were therefore confident that they were adequately safeguarding the public even when the patient was at large. There was need for an in-patient centre, or for a greater automaticity in facilities for treating patients in or from prisons. A minority of improved cases were discharged because, while no more could be done for the patient, he was not likely to commit any more offences. Others discharged themselves because their probationary period was over or they had to leave the district. When a patient was discharged not improved he would not necessarily return to crime but there was no scientific reason for supposing that he was cured.

Avoidable Difficulties in Treatment

Illustrating his argument by actual case histories Dr Carroll pointed out some of the directions in which the courts could help the medical psychologist if they wished. A girl was treated during a period of probation; she was not particularly neurotic and her mental disease, which was curable, was not the cause of her delinquency. Her cure would have required about two years, her probation period was six months. She was not a very willing patient, and at the end of the six months she broke off treatment. Some time later she was convicted of a repetition of the offence. The medical psychologist told the court that although the clinic could not promise a cure they were hopeful of one if a sufficient degree of compulsion could be applied to bring the girl under continuous treatment for two years. They tentatively suggested three years probation, or, if the court saw fit to imprison her, a sentence long enough to enable her to be adequately treated. The court unfortunately gave her six months. It was fairly certain that she would not return for treatment unless she were quite unable to obtain work. The opportunity had therefore been wasted for she would almost certainly repeat her offences. Dr Carroll said that he did not blame the court, for the Institute had not yet made its aims and principles clear to all magistrates. This magistrate had declared that the girl had been given a chance and had not taken it. This was an unfortunate remark to make to a person who needed treatment, without which she could not be expected to make use of opportunities.

In earlier years psychotherapists had supposed that compulsion was incompatible with successful treatment. This view had now been modified, for so far from being a hindrance compulsion had been found in some cases to be indispensable. The court could help the clinic by making treatment a condition of probation and by imposing so long a period of probation that the patient could not see the end of it as sufficiently near to encourage him to mark time until it came. On the whole the courts had been highly co-operative, they were the biggest source of the clinic's cases and its most enthusiastic supporters. Continuity of treatment was everything and one solution was to treat the patient in gaol. This was impracticable with an unpaid medical staff who could not find time to visit a prison regularly. It would, however, enable the clinic to treat hopefully a number of cases of serious crime.

A Statistical Approach

Published statements declaring that juvenile delinquency had increased were amateur in authority, Dr Carroll said, and were not supported by scientific evidence. The only correct approach to the problem would be an examination of all the available data by a committee of competent scientists including psychiatrists, statisticians, and sociologists who should be given every facility by the Government Departments concerned and have access to all the available data of the type of offences, the type of punishments and probation awarded, and the results obtained, correlated where possible with the social history and with the findings of a psychological examination. If several thousand cases were followed over a long enough period the conclusions would be reliable and the committee could state with confidence what social factors operated in producing juvenile delinquency and in increasing it, and what effect the modern methods had. They could also answer such questions as whether birching was good or bad and if good for what kind of cases. He hoped that the Home Office Committee on Corporal Punishment would recognize the need for this kind of data. If it were a committee of the usual kind its findings would probably not have much value. Such an investigation could not cost more than £20,000 and would probably not cost more than £3,000 or £4,000.

The causes of delinquency included precipitating or trigger causes predisposing causes and specific causes, in the absence of which no circumstances could produce delinquency. It was therefore futile to speak of delinquency as due to such causes as boredom and excitement over films for these were purely secondary. In ten or fifteen years psychologists might discover the predisposing factors in school children. Alfred Adler had for some years been given access to all the school children in Vienna and had picked out those who were predisposed to delinquency. Under a new political regime these facilities had been withdrawn. Scientifically the connexion was not proved but in fact juvenile crime had much decreased during this experiment and had risen again after it was discontinued. A similar experiment should be carried out in this country. A trained psychiatrist would have to be employed in each group of schools at about £1,000 a year but the result would be worth millions to the nation. It was highly probable that delinquency and neurosis had a common cause connected with the diffi-

in an approved school could not cure by itself. The medical psychologist's contribution was essential, and his advice should be taken before a child was sent to an approved school for a long term.

In conclusion, the CHAIRMAN expressed his gratification that the scientific treatment of delinquency had penetrated even into the darkest recesses depicted by Mr Albert Crew, the Recorder of Sandwich and Sir Hubert Bond, Commissioner of the Board of Control both members of the council. He hoped that sooner or later the value of the work would penetrate to that darkest of all recesses, the British Government. A new idea had always to be developed in England by a voluntary society and the Institute was doing arduous work of the utmost value.

THE ADRENAL CORTEX*

In a discussion which followed the reading of Dr W. N. Kemp's paper on the adrenal cortex, delivered recently before the Osler Society, Dr KINSMAN commented on the "thymic syndrome," stating that in his opinion the "breath holding spells," so alarming clinically, are part of that syndrome. "A child may have as many as ten or twelve such spells each day. The child holds its breath, turns blue, and collapses. The spells are most alarming. Radiographs in every case show an enlarged thymus. Speaking from my own experience, x-ray treatment does not clear up these symptoms. It does not reduce the size of the gland. I have now seven children over 2 years of age who have had marked breath holding spells—one had ten or twelve each day. The most of them had had x-ray examination which showed marked enlargement of the thymus. A series of x-ray treatments made little or no improvement in the spells. The children were then put on adrenal cortex, and in every case showed marked improvement. The most extreme case was at once reduced to one or two mild spells each day."

Dr MATTHEWS said he had had two children both 5 years old but with no symptoms of status lymphaticus. The chest plates of each showed a very large thymus. They were given suprarenal cortex and one month later the thymus in each could hardly be found. He hoped to try adrenal cortex for breath holding spells as he had never been satisfied with x-ray treatment in that type of case.

Dr SPOLIN spoke on the possible aetiology of the thymic syndrome. While he thought that there was some relation to thyroid dysfunction he was sceptical of the possibility of adrenal cortical dysfunction being aetiological related to the thymic syndrome (status lymphaticus). Dr Spolin explained the clinical results of cortical therapy reported by Drs Kinsman and Matthews as possibly due to some pharmacodynamic action of adrenal cortical therapy.

Because quinine cures malaria we cannot argue that malaria is caused by the absence of quinine. He pointed out that some cases of the breath holding syndrome recover spontaneously. He did not think that the presence of an enlarged thymus in dogs after adrenalectomy was of any significance because from his experience in post-mortem examination of pups thymic enlargement is a normal finding. Dr Spolin did think that cortical therapy might possibly be of therapeutic value (for pharmacodynamic reasons) in cyclic vomiting of otherwise healthy children.

Dr TAIT, in contrast to the first two speakers spoke highly of the benefits of x-ray treatment in cases of the thymic syndrome. In his experience as a roentgenologist he stated: "I have never seen symptoms persist where a full course of treatment has been given nor have I known of a child's resuming from enlarged thymus after x-ray had been given. When you have something (thymic syndrome) that is specific I would suggest a cure where there is an end organ."

Dr PITTS showed two specimens from the pathological museum, one a normal pair of infantile adrenals and the other a decidedly hypoplastic pair taken from a foetus with anencephalus. He asked the speaker to make some comment on these.

Dr CLEVELAND raised several questions. Why do the experimental animals show a coincident fall in chlorides and glucose? Is the cortical hormone active when taken by mouth? How does one account for the beneficial results of adrenal therapy (whole gland) reported by Dr Pusey in a case of acne with dysmenorrhoea? Are there any preparations of cortin which can be used by mouth or injection that are not of prohibitive price for patients of small means?

Reply to the Discussion

Dr KEMP said in his reply I wish to thank Dr Kinsman for giving adrenal cortical therapy a trial in cases of the so-called thymic syndrome, and also Dr Matthews for showing the efficacy of the cortex by mouth in reducing the size of the markedly enlarged thymus glands in a small series of cases. While it is true that Dr Kinsman's series of cases is small, yet it is a beginning, and in my opinion is very suggestive that the thymic syndrome (so-called) is in reality one form of clinical cortico adrenal insufficiency. Dr Spohn is sceptical of the part that I have assigned to the adrenal gland in cases of the thymic syndrome. However, I would point out that Dr Spohn has never tried this therapy in actual practice—he dismisses its significance on theoretical grounds alone. He says the beneficial results reported by Drs Kinsman and Matthews may be explained on pharmacodynamic principles. Would he so explain the benefits of thyroid therapy in cretinism and myxoedema? How can you explain the relief of "symptoms" by the use of cortin in adrenalectomized animals on pharmacodynamic grounds? The answer is that in the cases of the thymic syndrome treated with cortex and reported by Dr Kinsman, as in clinical myxoedema and experimental cortical insufficiency as well, the results of hormone administration are probably true examples of replacement therapy. Dr Spohn states, and it is a well known fact, that some cases showing breath holding symptoms improve spontaneously. This is as one would expect from a knowledge of adrenal development in infancy if cortico adrenal dysfunction were the cause. Dr Spohn was sceptical of the significance of the enlargement of the thymus gland invariably present in the dogs adrenalectomized by Banting and Gairns as reported in this paper. Dr Spohn has frequently made post mortem examinations on puppies and they have all had enlarged thymuses. The answer to this criticism is that the dogs used in the experimental adrenalectomies under discussion were not pups, and secondly, the thymic hyperplasia following adrenalectomy is definitely emphasized by such astute observers as Dr F. Banting and his co-worker Dr Gairns. I note that Dr Spohn thinks that cortical therapy may be of value in cyclic vomiting possibly from a pharmacodynamic action. The specimens of adrenal hypoplasia in a case of anencephalus demonstrated by Dr Pitts are very interesting. In anencephalus the pituitary gland is usually absent—hence the adrenals, with out the adrenotropic hormone of the pituitary, do not develop normally. Dr Cleveland has raised a series of interesting questions which I will attempt to answer briefly. In adrenalectomized animals there is a fall in blood chlorides early, due apparently to the inability of the kidney tubules to resorb sodium chloride. The fall in blood sugar is more of a terminal phenomenon and is probably related to hepatic dysfunction incidental to the loss of cortin. The cortical hormone is active by mouth although much larger doses must be given. In regard to the use of whole adrenal gland in the case of acne and dysmenorrhoea one can simply say that there undoubtedly exists a close functional relation between the adrenal cortex on the one hand and the gonads and the

pituitary gland on the other. To me it is quite reasonable that in certain cases, such as Dr Cleveland cited, ovarian and pituitary function are improved by the administration of cortical extract. Acne is a frequent accompaniment of pituitary dysfunction—hence the improvement in pituitary function due to the administration of the cortical extract may account for the cure of the acne. Dr Cleveland mentions the high cost of cortical extract. This is unfortunately true. As someone has said, only a millionaire can afford to have Addison's disease. Dr Cleveland's question in regard to the aetiological differentiation of the types of hirsutism in the female is somewhat beyond the scope of this paper, suffice it to say that in such cases of hirsutism the differential diagnosis is between pituitary basophilism (Cushing's syndrome), adrenal tumour, arrhenoblastoma of the ovary, and tumour of the thymus gland. The thyroid is not usually "in the picture" at all.

MODERN ADVANCES IN OBSTETRICS

At the invitation of the Torquay and District Medical Society, a joint meeting with the Devon and Exeter Medico-Chirurgical Society and the Plymouth Medical Society was held at the Torbay Hospital on May 13, with Dr J. M. JARVIE, ex-president of the Torquay Society, in the chair. The first of three opening addresses in a discussion on modern advances in obstetrics was given by Dr MARSHALL SCOTT of Exeter.

Analgesia in Normal Labour

Dr Scott concerned himself mainly with the conduct of normal labour. In the first instance he touched upon the importance of the psychological preparation of the patient from the earliest ante natal visit, when anxieties as to the pains and dangers of childbirth might be allayed by a promise that there would be no suffering sufficient to constitute a painful memory afterwards. This, he said, was all that could be promised to-day if drugs were not to be pushed to a point dangerous to both mother and child. Insomnia and restlessness might be associated with anxiety in the last month of pregnancy, chloral hydrate, say 15 grains, given nightly during the last fortnight might relieve this and also have a favourable influence on cervical dilatation. The requirements suggested by Reynolds in respect of drug administration in the first stage were that there should be a prolonged anaesthesia with a minimum of repeated dosage, sleep between the pains, no prolongation of the first stage, and no ill effect on the child. In the second stage drugs should be selected with a view to a short induction period, rapid elimination, avoidance of depression or inhibition of uterine contractions, harmlessness so far as the child was concerned, and simplicity of administration.

The accoucheur should have a clear idea as to the aim of his treatment, whether amnesia, analgesia, anaesthesia, or a combination of these conditions. He described his own practice in some detail.

A mixture of potassium bromide and chloral hydrate with 10 minims of tincture of opium was given at the onset of pain. This could be repeated in two to three hours if necessary or the administration of gas and air by Minnitt's apparatus begun. If cervical dilatation should prove unexpectedly slow the inhalations could be interrupted and rest assured with an injection of omnipon and scopolamine. In starting to administer gas and air he was guided more by the extent of pain than by the degree of dilatation of the cervix, though in a primigravida the onset of acute pain was found to coincide usually with a three-quarter dilatation. Gas and air sufficed for delivery in about 75 per cent of his cases a figure according with that given by the British College of Obstetricians.

In prolonged labour due to inefficient contractions in some cases with cardiac or pulmonary complications in cases in which gas and air proved inadequate and occasionally in trial labour he gave omnipon and scopolamine followed in about

two hours by rectal paraldehyde. The dosage of paraldehyde was regulated by body weight: a minimum of 8 drachms was given admixed with olive oil in the proportion of one ounce of the latter to each drachm of paraldehyde.

Coming to the technique of delivery, Dr Scott said that he always wore a mask, and in addition to putting on clean dry gloves he swabbed them with neat dettol for three minutes when any vaginal investigation was necessary. Whenever possible he preferred a rectal examination as a method better tolerated by the patient which allowed dilatation of the cervix to be followed readily in the majority of cases permitted repeated examinations without fear of infection, and which saved time, material, and manipulation.

Some Obstetrical Difficulties

Dr Scott then discussed the advantages of a timely Caesarean section in primary uterine inertia as against allowing the case to drift into a condition of dangerous exhaustion. Judgement in such an instance was difficult to make but rapid deterioration in the general maternal condition seemed to him an indication for abdominal section. Leyland Robinson and co-workers of the Liverpool school had published a small series of cases which suggested that oestrin might be valuable in promoting more powerful and regular contractions in these cases of inertia.

He referred to the anatomy of the pelvic floor and the damage resulting from violent deliveries or from prolonged over-distension when the head remained low in the pelvis for many hours. He advised the carrying out of an episiotomy in nearly every case in which the head had been visible at the vulva for half an hour. The incision under general or local anaesthesia was made from the fourchette and extended some three-quarters of an inch posteriorly laterally. During the puerperium he concluded, an effort must be made to maintain the tone of the musculature of the pelvic floor by the blending of rest and exercise.

Toxaemias of Pregnancy

Dr CHARLES CROFT spoke as a physician who invades obstetrics rather than as an obstetrician. It had been a matter of some wonderment to him that a study of the toxæmias seemed to have been taken up more by the academic type of physician with leanings towards biochemistry or endocrine therapy, than by the practising obstetrician. He believed that there was but one toxæmia of pregnancy which showed itself in sundry forms: impaired renal function perhaps with degeneration of liver cells was the associated pathological condition. There seemed to be no reason for regarding the megalo-cytic anaemia found in certain cases of pregnancy as related to toxæmia, and when in the toxæmia of pregnancy an anaemia of the secondary type occurred he regarded it as an associated condition rather than as a direct result of the toxæmia. Accidental haemorrhage although not infrequently occurring in the toxæmias of pregnancy could be explained by the presence of the raised blood pressure accompanying the toxæmia rather than by the liver disease.

hydatidiform mole, in which there was no foetus to consider as a factor. It had been stated that the majority of fatal cases of eclampsia occurred in July, August and September, but the significance of this was not clear. Although albuminuria was held to be the common denominator of the pregnancy toxæmias, Dr Croft considered that this should be replaced by the factor of raised blood pressure, which would often be found before the onset of albuminuria, headache, and vomiting, although not always before the appearance of oedema. A rising blood pressure pointed to the onset of eclampsia with more certainty than a raised reading which was stationary, eclampsia could occur with a blood pressure of 165 mm Hg, or be absent with one as high as 200 mm Hg.

Diagnosis and Treatment

The only clinical tests of value in determining the onset of liver damage were those establishing the presence of bile pigment in the blood or urine. Treatment was urgently necessary in any case in which vomiting and anorexia were continuous and resistant to routine measures, or when there was a progressive rise in blood pressure or a diminished urinary output, or anaemia in association with any of these.

The only hope there was of securing even moderately early treatment in cases of fulminating eclampsia was by giving a discreet warning to patients in respect of symptoms which might arise and which should be reported immediately. The recent investigation by the Ministry of Health revealed that of seventy-three deaths from eclampsia, in twenty-one instances the medical attendant was not considered to have given sufficient attention to the patient either because of his neglect to examine the urine and estimate the blood pressure, or to treat the patient himself or to secure treatment for her. As to what was regarded as adequate treatment we read that

monthly visits of women to the clinic are desirable during the early months of pregnancy, twice a month from the fifth to the seventh month and later at weekly intervals until the time of confinement. Dr Croft added that this routine seemed to be rather burdensome for the vast majority of cases.

In considering preventive treatment he said that irrespective of whether a free supply of calcium protected against toxæmia or not it was logical to ensure a sufficiency of this salt and of vitamin D to aid absorption in the diet of the pregnant woman. It was calculated that the woman required 16 grammes of calcium daily and that in the last twelve weeks of gestation the foetus required 25 grammes. Thus the customary one pint of cows' milk was inadequate. Once the toxæmia was established immediate transfer from the clinic to medical supervision at home was imperative, the patient being ordered to have complete rest in bed. A milk diet should be prescribed with vegetables especially those supplying iron. Despite the strictures of Witt he recommended saline aperients and also advised calcium alkali and glucose. Calcium given either by intravenous or intramuscular injection had been proved of value in eclampsia. Caesarean section was justifiable only on very rare occasions showing as it did a substantial

luteinizing hormone and the progestin, for the production of which in the pre-gravid and early gravid periods the anterior pituitary and ovary had been responsible. Further investigations had shown that in some cases of threatened abortion with evidence of a still living foetus the Aschheim Zondek reaction was negative. From this was argued absence of the luteinizing factor, and the administration of prolactin or of progestin developed as an obvious line of treatment.

Dr McCallum then mentioned the importance of a sufficiency of vitamin E in the treatment of habitual abortion. Routine examination should exclude pelvic deformity, uterine displacements, cervical tears, tumours, chronic nephritis, and syphilis. These conditions having been excluded, he gave injections of progestin, beginning with 2 mg (2 international units) twice weekly. This was continued up to the thirty-second week. When there was any sign of abortion threatening the patient was put to bed and daily injections of 5 mg. of progestin given for one week. In addition to the injections in preventive treatment, he gave one teaspoonful of wheat-germ oil daily for six months. Thyroid extract 1/2 grain each night was helpful, and calcium in some form was necessary, with a diet rich in vitamins. Rest in bed during the dates when the menstrual period would have been expected, a quiet life, and sexual rest were important considerations.

Disproportion

In discussing disproportion Dr McCallum said that in the slight cases the diagnosis was by no means a matter of certainty. Little or no dependence could be placed upon the measurements of the internal conjugate. On the other hand, radiographic mensuration with improved technique was becoming wonderfully accurate. Nevertheless it was still impossible to forecast the degree of possible moulding on the part of the foetal head, the extent of relaxation of the pelvic joints, or the strength of the uterine contractions. Thus an opinion could not be arrived at with certainty in many of these cases until labour had actually begun, but he advised a careful examination at the thirty-sixth week. If the head was engaged or engaging a normal labour might reasonably be expected. If the head was still floating an attempt should be made to push it into the pelvic brim. Failure to engage and obvious overlapping, the head being flexed, was a clear indication for Caesarean section. If the head could be pushed in or the overlap was slight he would advise re-examination in two weeks' time, under anaesthesia if need be. If disproportion was now absent or in a slight degree he would allow a trial labour. He emphasized the importance of remembering that one of the commonest causes of an unengaged head at the end of the term was the incomplete flexion associated with an occipito-posterior position.

In the discussion which followed Drs H K GRIFFITH W A ROBB A A GAIRDNER, R S COLDREY R A LATTEY G M GREIG C MACVICKER, and HORTON DATE took part.

BIOCHEMISTRY OF MILK SECRETION

The biochemistry of milk secretion was the subject of a paper read before the Royal Society of Arts on May 26 by Professor H D KAY, director of the National Institute for Research in Dairying, University of Reading. He also touched on the control of milk composition.

Structure and Blood Supply of Udder

Professor Kay first described the structure of the udder with its four separated quarters with separate teats through the end of which passed a narrow channel to a small cistern connected with a larger storage cistern in the gland proper. This larger cistern was connected again by some eight to twelve milk ducts which after successive branchings ended in minute collecting tubules,

with an enlargement or alveolus at the extremity of each, in which the milk was actually secreted. All the constituents of milk were brought to the mammary gland by the blood, indeed it was sometimes claimed that milk had evolved from a blood transudate. Two large arteries in the cow each supplied one half of the udder, and were divided into a number of smaller arteries and these into arterioles, and finally into capillaries, penetrating into every part of the mammary tissue and providing each alveolus and secreting cell with a rich blood supply. The blood in the capillaries brought with it not only the precursors from which the cell manufactured all the specific milk constituents but also the sugar required to provide energy for the synthesis and the oxygen necessary to burn the sugar and keep the cells in good functional order. These materials diffused out of the blood stream into the small spaces between the cells, and the cells took up from this liquid the substances needed for secretion and respiration and restored to it the waste products of their activity, which were eventually returned to the venous circulation.

Milk Secretion and Composition

The milk secretion was undertaken by the cells lining the alveolus, and their changes in shape during secretion might be observed microscopically. Beginning almost as cubical cells, they increased in length, granules and small fat globules accumulated, and presently something occurred—probably a rupture of the distended cell wall—whereby the secretion was extruded into the alveolar space as milk, the cell then returning to its original size and the cycle recommencing. With several repetitions of the cycle the storage spaces in the gland became full of milk. Differences in the composition of milk, said Professor Kay, were bound up with the differences in the stage of development at which the young were born. In species such as the horse, in which the newly born were advanced in development, the protein, fat, and bone forming salts of the milk were less and the sugar content greater, in species in which the young were helpless at birth the protein and fat were high and the lactose low.

The lecturer stressed as an interesting biochemical fact the considerable degree of constancy in the composition of milk of the same species, no matter, within limits, what food was given to the lactating animal. The cow possessed a mechanism whereby she could produce milk, if need be, at the expense of her body tissues. In health the constituents of the blood were maintained at a constant level, and the secreting cells of the mammary glands were more efficient than those of the other tissues of the body in taking what they needed from the limited supply in the circulating blood. He described it as astonishing that on a diet deficient in lime or phosphorus the mammary gland continued to secrete milk quite rich in these elements at the expense of the lactating animal's bones. The rarefaction of the mother's bones might continue until spontaneous fractures ensued. It was a fundamental biochemical question, but an unsolved one how even when the skeletal and muscular framework was suffering the blood level of lime and certain other essential food materials remained almost unimpaired, also what was the nature of the process by which the mammary cells especially of early lactation exercised this preferential taking up of materials from the blood.

Biochemistry of Low Quality Milk

The fact must be accepted that in many instances cow's milk might be below the legal standards—set by the regulations of 1901 at 3 per cent fat and 8.5 per cent solids other than fat—and yet be genuine milk. From the consumer's point of view this was of real importance for he might be obtaining a lessened nutritive value by 10 or 20 per cent. The quantity of milk which the modern "good" cow was expected to secrete might be 800 to 1,000 gallons per lactation (say 300 days) in other words the total solids which the modern cow as

a result of generations of careful selection almost entirely for volume production, secreted in her milk in a year (during a large part of which time she was also in calf) was four times the weight of the solids in her own body. The strain on the physiological and biochemical equilibrium must be very great. Some 300 to 400 gallons of blood circulated through the mammary gland for every gallon of milk secreted and a cow might secrete four to six gallons a day.

The lecturer considered it possible that breeding for volume was one of the factors responsible for low quality milk. An animal freed with this unnatural physiological strain would tend to avoid it in part by secreting more water and less of the other physiologically costly materials in her milk. Another factor was the widespread incidence of udder disease. Mastitis had been shown to lead to a marked change in the composition of milk.

Hormones and Milk Secretion

The growth of the mammary gland was doubtless largely controlled by hormones oestrin and progesterin being mainly concerned. Injection of the pituitary hormone prolactin also usually brought about a copious secretion of milk. The lecturer described an experiment in which thyroxine had been given to the cow. The result of its administration in the form of dried thyroid gland and especially as the pure crystalline hormone was to increase the yield and improve the chemical composition of the milk, the percentage of fat increasing by some 16 per cent, even the amount of non fatty solids was raised. The total yield of butter fat per day was increased in one of the cows by nearly 50 per cent.

A minor constituent of milk—namely the enzyme phosphatase—had been found to be an interesting biochemical index of the efficiency of mammary secretion. There was least concentration of phosphatase in milk at the height of normal lactation. After administering thyroid gland or thyroxine there was a marked fall in milk phosphatase a fall which persisted while the quantity and quality of milk remained high. When the thyroxine was withdrawn milk secretion fell and the phosphatase concentration rose again.

Vitamin Content of Milk

Local News

ENGLAND AND WALES

Joint Tuberculosis Council

At the May meeting of the Joint Tuberculosis Council twenty-two members were present. The honorary secretary Dr Ernest Ward announced that 750 copies of the council's memorandum *Tuberculosis Among Nurses* had been printed and the Medical Research Council was considering republication of the memoranda by Drs W H Tytler and Peter Edwards on *The Microscopic and Cultural Examination of Sputum*. After a discussion on the Empire Conference on the Care and After-care of the Tuberculous it was decided to form a committee comprising Dr S Vere Pearson (convener), Professors W W Jameson and S Lyle Cummins with Drs Jane Walker, J B McDougall, F R G Heaf and F W Goodbody to consider what help this council can give the Colonies in their effort to control tuberculosis. The question of holidays with pay was raised and it was decided to place this subject on the agenda for the next meeting.

Work of a Medical Charity

The annual general meeting of the Society for Relief of Widows and Orphans of Medical Men was held at 11 Chandos Street, Cavendish Square W, on May 19 with the president Mr V Warren F.R.C.S. in the chair. The report and accounts for 1936 were presented and adopted. The total income for the year was £5,392 2s 8d. During 1936 twenty-one new members were elected, nine died and one resigned. The total membership on December 31 was 275. During the year £5,275 was distributed in relief to the fifty-nine widows and nine orphans in receipt of grants. This is an increase of £1,000 over the previous year due to the increase of the number of widows. One widow who died during the year had been on the funds for fourteen years and had received from the society a total sum of £1,390. Her husband had paid a life subscription of £76 5s. on becoming a member.

home, which is very pleasantly situated in gardens by the sea was first used for children who needed ordinary convalescent treatment. Then, seven years ago, the rheumatic clinic at the Hospital for Sick Children, Great Ormond Street, reserved twenty beds in the home for children suffering from rheumatic affection of the heart and the results were so good that it was decided to allocate all the beds to the one complaint. Great Ormond Street reserving a further number, and beds also being reserved for other hospitals. A school was started for the children and in 1931 was recognized as a special school for child sufferers from rheumatic heart disease. A large part of the annual income is, of course, derived from hospitals and public authorities on account of services rendered to patients, but there is scope for voluntary giving and last year the income from this source was increased by some £500 as the result of a broadcast appeal. The home contains seventy-three beds, and the average residence of the children is 100 days. The cost of each patient per week, including establishment and financial charges, is £1 3s 5d on the average. Although few of the patients received are Sussex children, the home appears to enlist a great deal of local sympathy and interest.

INDIA

Indian Institute for Medical Research

The first annual report of the Indian Institute for Medical Research, Calcutta, covers the period from January 1, 1935, to March 31, 1936, and includes an account of the work in the diagnostic section and the departments of bacteriology, protozoology, biochemistry and nutrition, and chemistry, immunochemistry, and chemotherapy. As the result of study of the immunity problems connected with cholera and typhoid fever a potent anti-cholera serum has been produced, and further investigations are proceeding with reference to the concentration of the toxin and antitoxin concerned. A preliminary note by Dr H. Ghosh about this work appeared in the *British Medical Journal* of January 12, 1935 and a report of the further advances, by the same author, was published in the issue of May 9, 1936. It now seems probable that there are two different kinds of toxin in cholera, an endotoxin and an exotoxin, which jointly produce the characteristic symptoms. Predominance of one or the other determines whether the clinical picture is more particularly that of an early onset of vasomotor paralysis or of excessive purging. The mortality among the cases treated with the serum was 10.65 per cent., as contrasted with 21.6 in the remainder. Preliminary researches with typhoid toxin indicate the possibility of producing an effective anti-typhoid serum. Evidence has been forthcoming that the common bowel disorders of the natives of Bengal are related to the usual high carbohydrate contents of the dietaries which give rise to fermentation and hyperacidity in the intestine, with consequent toxæmia especially in children. In the department of protozoology a systematic study is in progress with regard to the problems of cultivation and immunity which have been but little considered hitherto. The objective has been to discover whether antigens consisting of pure parasitic bodies obtained by cultivation of protozoa or extraction of their protoplasm can induce immunity in the body of the host and so be of prophylactic and therapeutic value. An oriental sore vaccine has been prepared from freshly isolated strains of *Leishmania tropica* and has been found to have a high therapeutic value. An intradermal skin test for this disease has been devised. Vaccine treatment is also proving useful in post kala-azar dermal leishmaniasis. Another investigation is proceeding into the possibility of cultivating malarial parasites on suitable media in order to produce a prophylactic malarial vaccine. An attempt is being made to desensitize cases of eczema, asthma, urticaria and pruritus with suitable antigens and a few patients have

been treated satisfactorily with urinary protease. The department of biochemistry and nutrition has been largely concerned with vitamin C, the nutritional problems of middle-class families, the nature of the oxytocic hormone of the pituitary gland, and the respiration of bacteria. A survey of the nutritive values of Indian foodstuffs and dietaries is being conducted systematically. Certain common Indian fruits have been shown to contain unexpectedly large quantities of vitamin C, and it has been demonstrated that the amount of this vitamin in human milk can be appreciably raised by appropriate dieting. The dietaries of middle class families in Bengal are markedly deficient in proteins, vitamins A and B complex, calcium, and phosphorus. The department of chemistry has been trying to elucidate the mechanism of antigen-antibody combination from considerations of their rate of diffusion, osmotic pressure, viscosity, and the Tyndall phenomenon observed in their solutions. Equations have been defined which account satisfactorily for the neutralization of streptolysin, tetanolysin, cobra haemolysin, staphylolysin, diphtheria toxin, and crotalus toxin by their corresponding antibodies, as well as to the adsorption of specific agglutinins by typhus bacilli and the vibrios of cholera and to the adsorption of specific haemolysin by the erythrocytes of the ox and sheep. The diagnostic section has shown that there was a great increase in the incidence of amoebic infection during the year under review. Improvements in certain diagnostic techniques have been suggested, and many doubtful cases of leishmaniasis were identified by special cultural methods.

Madras Ophthalmic Hospital

The annual report for 1935 of the Government Ophthalmic Hospital, Madras, shows that as usual common conjunctivitis and various forms of cataract were the most common diseases, glioma and epithelioma were the two most frequent tumours, and 8,149 operations were performed. The daily average number of patients in 1935 was higher than in the previous year, and those who could not be admitted to the wards were accommodated on the verandas. Radium treatment was used in seventy-eight cases, mostly of epithelioma and trachoma. Special training was given to 254 medical students, including 150 who were candidates for the M.B., B.S. examinations. In addition, thirty-seven post graduate students attended the practice of the hospital. No major building operations were undertaken during the year under review, but various minor repairs and improvements were effected in the hospital itself and the residential quarters.

SCOTLAND

Health of Scottish Ports

At the annual conference of the Association of Port Sanitary Authorities held recently in Glasgow, Bailie James Crawford who presided, said that the living quarters for the crews on ships now being built on Clydeside were greatly improved in situation, design, and comfort even in excess of the standard desired by the association. The latter was freely consulted by the Government, and was also in touch with the International Maritime Service which had been set up to control the spread of infectious disease from country to country and had built up an effective service for protection against the introduction of such diseases as small pox, plague, and typhus fever. The more enlightened methods now practised he continued had abolished the old system of quarantine except in unusual circumstances and the association performed a number of functions such as detecting infection among passengers and crews of incoming ships, examining aliens, inspecting imported foodstuffs and sanitary conditions of ships, and applying measures for freeing ships from rats and other vermin. In a paper on Insect Pests on Ships, Dr William C.

Gunn of the Public Health Department, Glasgow, said that infested living quarters of the crews might be regarded as slums, and should be inspected with the same care as houses on land. Fumigation by sulphur dioxide or hydrocyanic acid would kill bed-bugs and other insects, but persistent cleanliness alone would eradicate such pests.

Provision for Mental Defectives in Scotland

Arrangements for the institutional accommodation of mental defectives in Scotland were transferred to county councils and town councils of large burghs by the Mental Deficiency and Lunacy (Scotland) Act of 1914. In consequence of the war, however, the General Board of Control allowed these provisions to remain in abeyance, and decided that for a time the institutions at Larbert and Baldownie should be regarded as national institutions receiving cases without preference from all over Scotland. The Board of Control has now decided that every local authority shall be required to comply strictly with the statute, either by establishing institutions in co-operation with other local authorities or by contracting with the managers of existing certified institutions. The chief public assistance officer for Stirlingshire, at a meeting of the Public Health Committee of that county, reported that an agreement had been entered into with the National Institution at Larbert and the Stirling District Asylum for the maintenance of 150 juvenile defectives. He said that there was in practice a serious difficulty in the case of low grade defectives because under the agreement only 10 per cent of the accommodation was reserved for such patients, and serious administrative difficulties arose in regard to the hopeless and helpless low-grade defectives whose parents even if willing, were quite unable to care for them. At the present moment there were actually twenty low-grade defectives in the county waiting for admission to Larbert asylum. Dr E. N. Reid, medical officer of health, said that there was a serious lack of accommodation for defectives who required constant supervision. It was resolved to request the Board of Control that an increase of the quota for low-grade defectives in institutions should be made.

The Late Dr. Adler

As recorded in last week's *Journal* Professor Alfred Adler who had been delivering a course of lectures on psychology at Aberdeen University, died suddenly while walking in Union Street of that city on May 28. At the time of his death he had still one lecture of his course to deliver in Aberdeen after which he intended to give similar courses in various other cities of Great Britain. He was assisted in his work by his daughter Dr Alexandra Adler of Harvard University who is to deliver some of the courses which her father had arranged to give. The memorial service at the crematorium, Warriston Road, Edinburgh, was attended by various psychologists belonging to this country and the Continent.

A. Sézary and A. Horowitz (*Bull. Soc. Franç. Derm. Syph.*, December 1936, p. 1761) report on thirty-nine cases of lichen planus treated with stovarsol. The drug was administered for six consecutive weeks and two tablets of 0.25 gramme each were given every morning on the first four days of each week. Of the thirty-nine cases eleven failed to complete the treatment, twenty-five were cured, and three improved. Itching was relieved after the first week and the rash began to fade after the third week, disappearing completely between the fourth and sixth weeks. In a few cases a second course of treatment was required and was given after an interval of a month. The lesions of the mucous membranes were more stubborn than those of the skin. Sézary and Horowitz consider that this treatment is convenient, free from complications and gives results as good as those obtained with other modern methods.

Correspondence

Bronchostaxis

SIR,—Before we can accept Dr John C. Roberts's interesting case (*Journal* May 22, p. 1069) as one which may be adequately described under this title, the after-history of this patient must be followed up for a few years. Otherwise it may lead to still further errors in diagnosis. As it is the tendency is often to explain haemoptysis away rather than to explain it. If a facile diagnosis of bronchostaxis is to become popular then an even larger number of cases of tubercle and growth will be missed, and further research on bronchiectasis and cystic conditions of the lung will be hampered. I am not denying that the condition may exist, but many of us who have seen cases of haemoptysis of obscure origin have found that the obscurity has been removed by later developments—I am, etc.,

London N.W. 1, June 3 F. G. CHANDLER, M.D., F.R.C.P.

Definition of "Arrested"

SIR,—It was with great pleasure that I read your remarks on the technical use of the word "arrested" in the annotation on the Midhurst Report. How often have I seen the bitterness of the disappointment when, in answer to the question "Am I arrested?" I have been obliged to answer "No." It is true that I have always been careful to explain that the word, as used medically, bore a different meaning to the common one. Often, indeed, I have been able to say that my patient's disease was not only not progressing but was now hindered by frail walls and widely spaced bars from making further ravages likely that it was the patient's duty to make that prison daily more secure, and so on. But a final interview is not the occasion to teach new definitions, and our great ally Hope once bewildered, takes a long time to re-establish herself. And all, maybe, because a positive spirit is made once a day.

As this practice may happen to continue for half a century with no harm to the patient, our break away from the generally accepted meaning of the word has always appeared to me to be not only cruel but also a relic of ignorance—I am, etc.,

FRANCIS JUPE.

Technique in Knee-joint Operations

SIR,—Surely my friend Mr Eric Lloyd (*Journal* May 15, p. 1015) provides a sufficient commentary on his technique for operations on the knee-joint when he naively writes "Stitch abscess occasionally occurs two or three weeks after the operation but clears up rapidly on removal or discharge of a small piece of catgut." Does Mr Lloyd not realize that his catgut is discharged because it is septic and that it is septic because it has been contaminated by the skin around his wound—for he seems to be reasonably careful about not handling his sutures. I must add that he is indeed lucky not to have met with disaster, for it appears from his description of the operation that the only catgut he uses is so "quite superficial" but actually through the capsule of the knee joint.

There is more in the Lane technique than mere "knife-and-fore" operating, and I am astonished that Mr Graham Simpson (*Journal* May 22, p. 1033) an ex-house-surgeon of Lane's, so completely failed to grasp the significance

cance of the "ritual" which he was privileged to see at first hand (I also was privileged to serve as Lane's dresser and house-surgeon)—I am, etc.,

London, W1 June 4

A S BLUNDELL BANKART

Treatment of Hernia

SIR—Your leading article in the *Journal* of June 5 says that "efforts have also been made of late to revive the treatment of hernia by injections into the sac" (My italics). This is quite erroneous, and none of us who carry out this treatment in this or any other country claim so to do. This fundamental and widespread misconception accounts for most of the opposition in this country. The arguments against injection treatment so lavishly poured into the ears of my patients before they begin the treatment are based on false premises all starting from this erroneous assumption.

I was christened in San Francisco on the four hundredth anniversary of Christopher Columbus setting sail to discover the New World, and I derive much comfort from the knowledge that my favourite hero was called the mediaeval equivalent of a b— fool by the wisest brains in Salamanca and Europe. He knew there was land where he was pointing though he had never seen it. I know there is land where I am pointing, and I have seen it, and so have the other members of our profession who have followed the technique I have described in this *Journal* and elsewhere. The evidence on page 1159 of your issue of June 5 is all the more gratifying because it comes from someone quite unknown to me—I am, etc.,

London, W1, June 5 ST GEORGE B DELISLE GRAY

Intra-epidermic Vaccination

SIR—I have read with interest Dr E R Peirce's article on intra-epidermic vaccination (*Journal* May 22, p 1066), and the letter in your next issue by Dr J Pickford Marsden (May 29, p 1139). The method practised by Dr Peirce, however, does not materially differ from that described by Bryce in 1809, where he recommended introducing the point of a fine lancet the eighth part of an inch merely under the cuticle. Many others since then have described methods of so-called intra-epidermic vaccination by puncturing the epidermis with a lancet, chisel, or needle, but Dr Peirce is more bold when he states in his article

the technique is exactly similar to a Schick or a Dick test: a straight solid sterile needle is held almost parallel with the skin and the point is inserted gently through the drops of lymph under and along the epithelial layer for about a sixteenth of an inch and immediately withdrawn.

Now Dr Peirce must be fully aware that this is not in the least like the Schick or the Dick test. I draw attention to this fact not from a critical point of view but because I have practised intradermal vaccination for some years both in vaccinating large numbers of contacts and as a routine in hospital practice in both patients and staff and my method is similar to the Schick or the Dick test. My technique is as follows:

I break off both ends of the glass tube containing the lymph and with a 1-cm. all glass syringe fitted with an ordinary hypodermic needle insert the needle into one end of the tube and suck the lymph into the syringe. I now fill the syringe to 0.25 ccm. with sterile water. I then discard the hypodermic needle and replace it by a fine skin test needle and proceed to vaccinate the patients by injecting intradermally a small quantity of this lymph emulsion raising a wheal in exactly the same manner as in the Schick or the Dick test.

The best method, as Dr Marsden points out, is the method which admits of the least possible chance of failure. I maintain that my method, provided the lymph is active and the patient susceptible, cannot fail to give a successful vaccination.

I have not been able to get a "take" by the scarification method in any case "negative" by the intradermal injection, but I have had many cases of successful vaccination by the latter method immediately following a negative result by scarification.

This method can be applied with absolute surgical asepsis. There is little or no chance of secondary infection, which is almost always associated with the open scarification method, and which is in a large part responsible for the unsightly scar. There is a minimum of local or constitutional reactions. No dressing is necessary. The size of the pock and hence the resultant scar can be controlled by the amount injected. I find that adult patients much prefer this method of vaccination—I am, etc.,

London SE1 June 5

ROBERT G HENDERSON

SIR—The differences between Dr Marsden and me are largely due to different points of view. As a port medical officer I am concerned with small pox contacts who will disperse at the earliest opportunity, for that reason I must employ a method of vaccination which not only gives protection to those who need it, but tells me at the earliest moment whether the person vaccinated is susceptible or not. This information is not only wanted by me, but also by the medical officers of health of the districts to which the contacts are proceeding—I am, etc.,

Liverpool, June 7

EDWARD R PEIRCE

Angina Innocens

SIR—I read with much interest the article by Dr Geoffrey Bourne (*Journal* April 3, p 695) and the letter by Dr Fitzgerald Peel (May 22, p 1088) in your correspondence columns. I am inclined to disagree with Dr Peel, for I consider that the use of the term "angina innocens" in explaining the malady to the patient is a particularly happy one, as it brings out the salient features of the affliction as experienced by him together with its comparative harmlessness or innocence, a vital matter on which to reassure him.

Dr Fitzgerald Peel further says that it is rarely, if ever, necessary to give a name to the syndrome in talking to a patient. My experience has been to the contrary. I find that the intelligent patient likes to know what is the matter with him. If a doctor explains a syndrome to a patient he does so as simply as possible, and if in the end he can give it a name nothing pleases the patient better. If the doctor cannot name the disease the patient is apt to think that either the doctor has not taken him into his confidence on an all important matter in therapeutics, or that he does not fully understand his condition or that it is a very rare one and such an impression is likely to hinder recovery. This applies particularly to heart disease in which the patient's state of mind is often so important—I am, etc.,

CHANDU LAL MAHOTRA

SIR—The clinical study of cardiac pain by Dr Geoffrey Bourne (*Journal* April 3, p 695) is a welcome addition to a difficult subject. Under the term "angina innocens" he would include spasmodic hysterical vasomotor or syncopeal and toxic angina. Spasmodic angina is difficult to differentiate from angina of effort, as in both types

the attacks are sometimes due to indigestion, emotion, or cold, and all that we can say is that in the absence of cardiac and vascular disease the prognosis is good. The hysterical type or pseudo-angina is not difficult to diagnose as the mental condition dominates the picture. On one occasion I saw three women suffering from angina at the same time—the mother died in the attack and one daughter had typical spasmodic angina, while the other daughter suffered from hysterical or pseudo-angina. The syncopal type, described by Nothnagel as vasomotor angina, in my experience has been marked by coldness and numbness of the limbs. The pain is as intense as that of angina of effort, but the cases are usually in women at the menopause.

It would be unfortunate if the term "angina innocens" were used without a further separation according to the clinical picture—I am, etc.,

Animal Pathology

SIR,—In the annotation at page 1165 of the *Journal* of June 5 it is stated. We may reasonably ask ourselves whether disease in animals is being adequately studied in this country. It might have been supposed that the common diseases of our principal fauna were well known, but we may now wonder whether there are not other species, especially among wild animals and perhaps birds, whose entire pathology is an unexplored field.

I was privileged to share with the late Dr J G Adams a deep interest in wild birds. Adams told me how this and his work with Metchnikoff had quickened his desire to compare human disease with disease in our domesticated and wild fauna, a desire he had found little opportunity of satisfying. He shared with the late Sir Clifford Allbutt the conviction that more knowledge of comparative pathology was required for our understanding of disease in man, but he feared that for such pioneer work there would be no security and little or no prospects. Encouraged by Adams I embarked on comparative pathology and I have acquired sufficient experience unhesitatingly to assert (1) that there is a considerable corpus of knowledge of disease in our domesticated horses, cattle, pigs, sheep, goats, dogs, cats, and poultry (2) that a large amount is known of disease occurring naturally among laboratory animals, (3) that during the past ten years several workers have contributed much to our knowledge of disease among the animals farmed in Great Britain for fur (for example, silver fox, mink, marten, fitch, rabbits and nutria) and (4) that to those familiar with the subject there is a not insignificant amount of data on disease in the wild fauna of this country. There are species of our wild fauna of whose pathology little appears to be known—for example voles, shrews, dormice, field-mice. Charles Elton and his colleagues are to be congratulated on their pioneer work in the ecology of these small rodents. My own experience of disease in our wild fauna has been derived mainly from birds, however I am not unfamiliar with some of the pathology of squirrels, fox, rabbit, hare, blue hare, and stoat while occasional specimens of wild cat, hedgehog and badger have been received.

I have had the temerity to mention my work not because I see clearly what to make of it all but because it has brought me into close touch with other workers on the wild fauna. They like myself do not earn their living by such pursuits, this may explain why these unfamiliar with the subject regard it as an unexplored field. If

the writer of the annotation should reply that the work done and proceeding is "inadequate" to the needs of pathology I should agree with him. Some day, perhaps, those in authority will recognize that there is something after all in Adams's notions, and in the work of John Hunter, Tegetmeier, Bland-Sutton, Wilson, Frank Colyer, Pillers, Henry Gray, and many others. Some day, perhaps, finance will be made available to establish an institute of comparative pathology where disease in our domesticated and wild fauna can be studied for the service of the science of medicine—I am, etc.,
